STUDIES ON HOST-VIRUS INTERACTIONS IN THE CHICK EMBRYO-INFLUENZA VIRUS SYSTEM*

I. ADSORPTION AND RECOVERY OF SEED VIRUS

By WERNER HENLE, M.D.

(From The Children's Hospital of Philadelphia (Department of Pediatrics, School of Medicine, University of Pennsylvania), Philadelphia)

(Received for publication, January 4, 1949)

Most studies on the interrelationships between animal viruses and their respective hosts have been restricted to an analysis of the response to infection of the host animal as a whole, or of the affected organs. If one could study host-virus interactions in individual host cells, or groups of identical cells, it is obvious that much could be learned regarding the mechanism of infection. There are not many animal host-virus systems available at present which lend themselves as readily to such analyses as do bacterial host-virus systems, but the entodermal layer of the allantoic sac of the developing chick embryo infected with influenza virus provides an approach to such a system, although it is far from ideal.

In the analysis of the mechanism of infection of the cells lining the allantoic cavity of the chick embryo by influenza virus, one may reason, *a priori*, that the infectious process is divided into at least four major steps: (a) adsorption of the virus onto the host cells; (b) entrance of the virus into the cells;¹ (c) propagation of the virus within the host cells;¹ and (d) liberation of the newly formed virus from the cells. This division is supported, in part, by a number of previous studies which have been concerned predominantly with one or the other of the phases of the infectious cycle (1-3).

It is the aim of this series of studies to analyze further the individual steps

* The work described in this paper has been supported by a grant-in-aid from the United States Public Health Service.

¹ Although it has not been definitely proven that the influenza viruses propagate within the host cells, the following points may be cited in favor of such an assumption: intracellular multiplication has been demonstrated for other agents of this class, and it is unlikely that the influenza viruses are exceptional in this respect. The presence of antibody in the allantoic fluid does not prevent propagation of virus in the allantoic membrane (5). Irradiated, interfering influenza virus, and possibly also fully active virus, exerts a profound effect on the functions of the host cells in that it prevents further growth of the allantoic sac (3), conceivably by interaction with an enzyme system within the cell necessary for both virus and host cell growth.

of the infectious process. The first paper is concerned particularly with the adsorption of the seed virus onto the cells of the allantoic sac. The data to be presented here have in part been extracted from experiments conducted for various other purposes, which will be discussed in subsequent papers of this series (4, 5). They show that on the average, about 70 per cent of the injected virus is adsorbed onto the host cells, yet only a small percentage of the adsorbed virus can be demonstrated as active virus in suspensions of the allantoic membranes in spite of attempts to improve the yield by various means, or to find the missing virus in other structures of the egg. Thus the suggestion appears justified that the major portion of the infecting agent, upon intimate contact with the host cells, is so bound or becomes so altered as to be undetectable by infectivity titrations. The small fraction of active virus demonstrated in the tissue suspensions may represent virus which remains on the surface of the membrane and which possibly does not increase in quantity.

Materials and Methods

Preparations of Virus.—The PR8 strain of influenza A was mainly employed in these experiments, and only a few tests with the Lee strain of influenza B are included. The seed virus was prepared by inoculation of 0.2 ml. of infected allantoic fluid in dilution 10^{-7} into 10-day-old chick embryos by the allantoic route. After incubation of the eggs at $36-37^{\circ}\text{C}.$ for 48 hours, they were chilled for 1 to 2 hours at $4^{\circ}\text{C}.$, and the allantoic fluids were collected. They were distributed in 1 ml. amounts into ampules, which were sealed in an oxygen flame. After quick freezing, the ampules were stored in a dry ice chest. If 10^8 or 10^9 ID_{50} was required for injection, freshly prepared seed was used (5).

For experimental purposes, the seed culture was diluted in broth so as to contain the desired number of ID_{50} per 0.2 ml. inoculum, and injections were made by the allantoic route into 12-day-old chick embryos. Following incubation of the eggs, aliquots of the allantoic fluids were collected during the constant periods² (2), after removal of the shell over the air sac, by needle and syringe without previous chilling of the eggs. When quantitative data were needed, the remainder of the allantoic fluid was poured off and measured in a graduate cylinder. The allantoic membranes were harvested during the first 3 hours after infection in the case of the PR8 strain, and during the first 5 hours in the case of the Lee strain, corresponding to the constant periods as obtained in membrane suspensions² (4). After removal of the allantoic fluid as described, a cross-cut was made with scissors into the shell membrane and the underlying chorioallantoic tissue, the embryo, yolk sac, and albumen were discarded with precautions to sever the connections of the allantoic sac close to the unwanted structures. The allantoic sac at this stage of the embryonic development adheres to the shell membrane, and thus offers the opportunity to wash it thoroughly *in situ*. The eggs were each filled with sterile buffered saline solution (40 to 50 ml.), agitated, and the wash fluid poured off. After

² Following infection, a certain amount of seed virus is found in the allantoic fluid and in suspensions of allantoic membrane. This quantity remains constant for various periods of time until a sudden rise in infectivity is noted. The period of constancy varies, depending on the type of virus used and the material tested. In the allantoic fluid, the constant periods extend over 5 to 6 hours in the case of influenza A, and over 8 to 10 hours in the case of influenza B virus. The corresponding figures for suspensions of allantoic membranes are 4 and 6 hours, respectively.

repetition of this procedure, the membranes were removed from the shells, pooled, and washed twice more in Petri dishes containing approximately 50 ml. of buffered saline solution each. The tissue was then emulsified in chilled semimicro Waring blenders either immediately or after various periods of storage in the cold, as will be described. For each membrane, 5 ml. of buffered saline containing 100 units of penicillin and 100 μ g. of streptomycin per ml. was used. Each suspension was prepared from at least four and usually six membranes. Blending was carried out as a rule for 3 minutes, but was varied in a few instances, as will be described. Some of the suspensions were titrated in chick embryos without centrifugation; the majority, however, were clarified by spinning at 2000 R.P.M. for 20 minutes.

Titration of Virus.—The virus preparations were diluted in tenfold steps in broth containing 100 units of penicillin and 100 μ g. of streptomycin per ml. Ten- or 11-day-old chick embryos were injected with 0.5 ml. of the various dilutions. The embryos were further incubated at 36–37°C. for 72 hours when 0.4 ml. of allantoic fluid was removed from each egg, transferred to individual test tubes, and tested for hemagglutinating activity as an indication of the presence of virus by addition of 0.2 ml. of a suspension of 1 per cent chicken red cells. The 50 per cent infectivity end-points were determined according to Reed and Muench. For titrations of the seed used in the various experiments, ten embryos were employed per dilution, for the experimental preparations, five each. However, since most of the data recorded in this paper are part of experiments to be discussed subsequently, usually two to five titrations during the constant periods were available which were combined for this analysis. Thus, the figures given for the experimental groups are based on titrations with at least ten and sometimes with up to twenty-five eggs per dilution.

Calculations.—In order to determine the degree of adsorption of the injected virus onto the host cells, the following data became available in the tests: (a) the amount of seed virus injected; (b) the quantity of free virus in the allantoic fluid during the constant period; i.e., the ID_{50} /ml. found multiplied by the number of milliliters collected from these eggs. Subtraction of (b) from (a) corresponds to the amount of virus presumably adsorbed. The total amount of virus in the allantoic membrane was calculated by multiplying the ID_{50} /ml. by the volume of suspension (5 ml. per egg membrane).

EXPERIMENTAL

A few data on adsorption of influenza virus onto the cells lining the allantoic sac have been included in previous publications employing either the hemagglutination test (1, 3) or infectivity titration for assay (2). Additional information concerning this phase has been accumulating in subsequent experiments devised for other purposes (4, 5). As can be seen in Table I, in twenty-seven experiments employing the PR8 strain and eleven using the Lee strain, adsorption varied within certain limits as determined by the difference between the number of ID_{50} injected and the number of ID_{50} recovered free in the allantoic fluid of the injected eggs during the constant period. Average adsorption amounted to about 70 per cent of the injected seed virus, with a maximum at 96 and a minimum at 42 per cent.

It was expected that the degree of adsorption would vary to some extent with the quantity of virus injected. However, within the range of ID_{50} employed as inoculum, the average percentage of adsorption did not differ significantly, as seen in Table II, and the same extent of variation was noted regardless of whether 10^9 or 10^2 ID_{50} was injected.

The difference between the amount of seed virus injected and the quantity of virus recovered in the allantoic fluids of the injected eggs during the constant periods was relatively small in terms of logarithmic units, as seen in Table III. The average difference amounted to log 0.40, minimally 0.24 and maximally 0.63. The accuracy of such infectivity titrations has been studied extensively by Knight (6), who found on statistical analysis of replicate titrations of preparations of influenza virus that the chances are 19 out of 20 that differences in end-points of 0.37 and 0.62 logarithmic unit are significant in titrations employing ten embryos and five embryos per dilution, respectively. In the

experiments presented, the results of the seed titrations, using ten embryos per dilution, were compared with the combined results of two to five titrations of various allantoic fluids collected from the injected eggs during the constant periods. These employed five embryos each per dilution, and were corrected for the volume of fluid found in order to obtain the total amount of virus recovered. Although the recorded differences may seem to fall into the border region of statistical significance, the following points should be taken into account in judging the validity of the conclusions tendered: (a) All experiments showed differences in the same direction. These included the sixteen tests shown in Table III, which involved titrations of both the allantoic fluids and of suspensions of allantoic membranes, and an additional twenty-two

experiments in which only the allantoic fluids were studied. Thus, in thirty-eight experiments, the same trend was noted. (b) The results of the several five embryo titrations of the allantoic fluids harvested during the constant periods of the individual experiments, which were corrected for the total volume collected and which were combined for this analysis, agreed within log 0.25 on the average, with a maximal spread of log 0.50. On occasion, if only

* ID₅₀ per ml. multiplied by the volume of allantoic fluid collected.

† Determined by the difference between the values shown in columns 2 and 3.

two titrations were performed, identical results were obtained. Thus, these results fell well within the range of reproducibility given by Knight for employing this number of embryos per dilution, in spite of the additional variable in measuring the total volume of allantoic fluid present in the injected eggs. The amounts of fluid found in individual eggs as well as the averages of pooled fluids from different groups of eggs in an individual experiment showed variations within a range of from 8 to 10 ml. Small quantities of allantoic fluid were retained by the eggs, but these appeared negligible considering the large volumes of fluid present in 12-day-old embryos. This error possibly was

counteracted by the addition to the allantoic fluids of small amounts of blood, or the occasional inadvertent admixture of some amniotic fluid. (c) The same order of difference between the amount of seed virus injected and that recovered was noted in experiments in which the quantity of seed varied over a wide range; *i.e.*, the difference was independent of the number of tenfold dilutions required to reach the end-point of infectivity.

These various considerations of the limitations of the technics employed fail to discredit the conclusion that the average value of adsorption of 70 per cent is probably nearly correct. In order to establish this value more firmly, it was thought advisable to determine the amount of virus that could be demonstrated in suspensions of allantoic membranes following adsorption. However, when such tissue preparations were titrated in chick embryos simultaneously with the allantoic fluids collected from the same eggs, it was found that only a small percentage of the amount of virus calculated to be adsorbed could be demonstrated. As seen in Table III, only between 1 and 5 per cent of the adsorbed, or 0.8 to 3.5 per cent of the injected virus could thus be found. The limitations of experimental procedure and accuracy discussed above hold, of course, also for these tests. Additional sources of variation are to be found in the fact that the allantoic sacs may, to some extent, vary in size at this stage of development. Furthermore, this tissue may not be separable in its entirety, and small fragments of it may escape with the other structures of the egg when they are discarded. However, these additional sources of error could hardly account for the extent of the discrepancies in the virus assay.

Attempts to clarify this problem may be divided into several steps: efforts (a) to demonstrate an antiviral effect in allantoic fluid; (b) to improve the handling of the tissue and with it, the yield of virus; (c) to search for an inhibitor of virus activity in the tissues; (d) to demonstrate a loss of virus in the process of preparing membrane suspensions; (e) to find virus in other structures of the egg as a result of possible rapid resorption of the agent; and (f) to determine whether the non-adsorbed seed virus differed from the adsorbed agent in properties leading to the combination with the host tissue.

It was considered unlikely that allantoic fluids of 12-day-old embryos possess antiviral activities in view of the stability of infectivity in this medium (7), and the constancy of the virus titer in the allantoic fluid during the first few hours after infection (2). In agreement with this past experience, addition of known amounts of virus to normal allantoic fluid of 12-day-old chick embryos *in vitro* and incubation at 37°C. for 1 to 6 hours, did not reduce the infectivity as compared with that of control preparations of virus in broth. This result is in agreement with recent observations by Svedmyr (8) and by Hardy and Horsfall (9) who demonstrated the presence in normal allantoic fluids of a component which may prevent hemagglutination but apparently does not affect infectivity.

All attempts to increase the yield of virus from allantoic sacs have failed. It did not matter whether the suspensions of the tissues were prepared immediately following harvest or after the membranes had been stored in the cold at 4°C. for 24 hours, or at -15°C. for several days; the results of the titrations in chick embryos gave figures well within the accuracy of the technic. Variation in the method of emulsification of the tissue, likewise, failed to increase the virus titer. Grinding of the tissue with mortar and pestle, using alundum as abrasive, was inferior to the use of the Waring blender. Varying the time of blending, it could be seen (Table IV) that after 1 minute, and regularly after 3, maximal titers were obtained, and further treatment in the blender did not release significant quantities of additional virus. Microscopic examination of smears prepared from such suspensions revealed only occasional individual or small clusters of intact cells. Blending for 3 minutes was adopted

TABLE IV

Effect of Variation in the Time of Grinding in the Waring Blender on the Yield of Virus (PR8) from Allantoic Membranes

Preparation No.	ID ₅₀ per ml.			
	Run in Waring blender for			
	1 min.	3 min.	6 min.	10 min.
1	—	10 ^{0.97}	10 ^{0.93}	—

as the routine procedure. Repeated freezing at -70°C. and thawing at 37°C. prior to emulsification did not alter the results. Some of the crude tissue suspensions were exposed to intense sonic vibration³ for periods up to 60 minutes. This procedure, which does not affect the titers of infectivity and hemagglutination of virus contained in allantoic fluid, did not improve the yield in the tissue emulsions (Table V), although the debris sedimentable by low speed centrifugation at 2000 R.P.M. for 20 minutes was minimal as compared to the sediment obtained from non-treated suspensions, indicating the more complete emulsification of the tissues. Crude suspensions were kept at 37°C. for 1 to 2 hours to effect any possible elution of virus from tissue fragments or dissociation of virus aggregates, again to no avail. Suspensions of tissue were incubated at 37°C. for 4 hours with 0.01 per cent trypsin.⁴ The virus titers of

³ The sonic oscillator used was manufactured by the Raytheon Manufacturing Company, Boston.

⁴ The amount of trypsin used was sufficient to digest in 1 hour at 37°C. a 2 per cent solution of gelatin to such an extent that it no longer solidified at 4°C.

the digested preparations were similar to those of the controls not treated with the enzyme. When centrifuged and non-centrifuged suspensions of allantoic membrane were compared in their infectivity, no significant differences in titer were noted (Table VI), and the sediments contained less activity than the supernate. Centrifugation at 2000 R.P.M. for 20 minutes was, therefore, adopted as routine procedure. The virus titer in suspensions of membranes was quite stable at 4°C., and it did not matter whether titrations were done

immediately following preparation or after storage for 1 to 2 weeks at 4°C. (Table VII). This stability permitted repetition of titrations in case unexpected or questionable results were obtained in the first assay.

Another set of experiments was directed toward the demonstration of inhibitors of virus activity in the tissues. To avoid admixture of red blood cells or fragments thereof, as well as of serum which frequently contains a non-specific inhibitor of the hemagglutinating activity (10-12), membranes were perfused with buffered saline solution before harvest. Comparison of suspensions of perfused and non-perfused membranes did not reveal a significant difference in

virus titer. Addition of known amounts of virus to normal membranes immediately before blending or after their emulsification and subsequent titration of the preparations gave titers closely similar to those obtained with the same amount of virus added to broth in the same proportion.

As a further possibility, it was considered that virus may be eluted from the tissue in the process of preparation. Although elution has not been demonstrated as yet from the allantoic sac of the living chick embryo, it does occur when the tissue is killed by formalin (13). It was possible, therefore, that during the washing of the membrane, conditions became favorable for elution. However, titration of the first and second wash waters yielded quantities of virus corresponding to about 1 and 0.1 per cent, respectively, of the total amount in the allantoic fluids, indicating that the amount of virus found in the wash water most likely corresponded to the amount of allantoic fluid left in the eggs when washing commenced.

Finally, attempts were made to demonstrate virus in structures other than the allantoic membrane, in view of the possibility that some of the virus might become rapidly resorbed. However, no evidence for such an occurrence has been obtained in the past (3), and the present experiments have confirmed these data. No virus was found in the blood withdrawn from the embryos in the first few hours after infection. Suspensions of embryo and yolk sac contained less than 1 per cent of the activity of the allantoic fluids of the corresponding eggs, and it is likely that this amount reflected the degree of contamination of the test tissues with residual allantoic fluid during harvest.

The uniformly unrevealing tests presented above suggested that the seed virus left free in the allantoic fluid during the constant period might differ from that adsorbed onto the tissues by its combining properties. However, when allantoic fluids, collected 2 hours after injection of high titered seed, were employed for subculture, it was found that again about 70 per cent of the virus was adsorbed within 1 hour after injection. The constant period, likewise,

conformed to the usual experience in that 6 hours elapsed until new generations of virus were released into the allantoic fluid.

DISCUSSION

The data presented have shown that regardless of the quantity of virus used, about 30 per cent of the influenza virus injected into chick embryos by the allantoic route remains free in the allantoic fluid of the infected eggs. Since all attempts to demonstrate in allantoic fluid an inhibitor for the infectivity of virus particles have failed, it must be concluded that the remaining 70 per cent of the seed virus has been adsorbed onto the tissues of the allantoic sac. Adsorption of influenza virus onto red cells usually is far more complete (14) probably as a result of the fact that the virus and adsorbing cell are both suspended and intermixed in the same medium, offering a greater chance for the agents to collide. In the allantoic sac system, contact between virus and host cells can be made only at the fluid-tissue interface. The equilibrium between adsorbed and free virus is established usually within one-half to 1 hour after infection (2).

Attempts to demonstrate the adsorbed virus in suspensions of allantoic membrane met with only partial success. It has been impossible to detect more than 1 to 5 per cent of the amount of virus, and all efforts to improve the yield have failed. These included: emulsification of the tissues in the Waring blender for extended periods of time; exposure of the crude suspensions to intense sonic vibration which resulted in more complete emulsification; digestion of the crude suspensions with trypsin; incubation of the emulsions at 37°C. for 1 to 2 hours to effect elution of virus from tissue debris; perfusion of the tissue prior to harvest in order to avoid admixture of inhibitors possibly present in the blood stream; search for inhibitors of viral activities in suspensions of normal allantoic sacs; and, finally, exclusion of possible resorption of virus and spread to other structures of the chick embryo. None of these tests has furnished a clue to the missing virus.

There remain three possibilities to be considered: (a) The methods of emulsification are not effective enough as yet to disrupt all the infected cells or to free all the virus from fragments of the tissue, so that it escapes detection. (b) Although emulsions of the tissue do not reveal an inhibitor for virus activity, the intact cells may be able to cause inactivation of some of the seed virus. In that case, the missing virus would have to be considered waste, and the active virus found in the tissue would correspond to the "infecting" agent. Finally, (c), the seed virus, upon the intimate contact with the host cells which leads to propagation, becomes, as a result, altered in such a way that it can no longer be demonstrated. The active virus, in this case, would represent "superficially adsorbed" virus which does not increase in quantity. This last point gains in importance, in view of the fact that a major portion

of the active virus in the membrane is accessible to the action of neutralizing antibody, as will be demonstrated in a subsequent paper of this series (5). The last point appears to be borne out, too, by results obtained in bacterial host-virus systems in which it has been found impossible, thus far, to recover the infecting agent from the host cell in the early stages of the infectious cycle (15).

SUMMARY

Upon injection of active influenza A or B virus into the allantoic cavity of the developing chick embryo, an average of only 70 per cent of the agent was adsorbed onto the tissue, as measured by the difference between the quantity of virus injected and that found free in the allantoic fluid of the injected eggs during the constant period. The degree of adsorption was similar, regardless of whether 10^9 or 10^2 ID₅₀ of active virus was injected.

Attempts to demonstrate the adsorbed virus in suspensions of the infected tissue met with partial success only in that not more than 1 to 5 per cent of the amount calculated to be adsorbed was actually found. All efforts to increase the yield of virus have failed. These results led to the suggestion that the seed virus, which participates in the propagation, becomes altered in such a way that it no longer may be demonstrated by infectivity titrations, whereas the active virus found represents superficially adsorbed virus, which does not multiply.

STUDIES ON HOST-VIRUS INTERACTIONS IN THE CHICK EMBRYO-INFLUENZA VIRUS SYSTEM*

II. THE PROPAGATION OF VIRUS IN CONJUNCTION WITH THE HOST CELLS

By WERNER HENLE, M.D.

(From The Children's Hospital of Philadelphia (Department of Pediatrics, School of Medicine, University of Pennsylvania), Philadelphia)

(Received for publication, January 4, 1949)

In previous studies on the mechanism of infection of the entodermal layer of the allantoic sac of the developing chick embryo by influenza viruses, a somewhat indirect approach has been employed. It has been possible to deduce certain facts from observation of changes in the infectivity and hemagglutinating activity of allantoic fluids bathing the infected tissues. Thus it has been found that only about 70 per cent of the virus injected into the allantoic sac becomes adsorbed, as demonstrated by the difference between the quantity of virus injected and that found free in the allantoic fluid in the first few hours after infection (1). The titer of the non-adsorbed virus in the allantoic fluid remains constant for different periods of time depending on the type of virus injected. The constant periods in case of strains of influenza A virus extended over 5 to 6 hours, those of the influenza B strains over 8 to 10 hours (2, 3). At the end of these periods, during which it is presumed that the agents are propagating in association with the host cells, the titer suddenly increases as newly formed virus is liberated, terminating the first cycle. The released virus will immediately initiate a second cycle as part of it is adsorbed onto some of the residual non-infected host cells. If adsorption is prevented by the presence of irradiated interfering heterologous virus, injected during the constant periods, all the released virus remains free in the allantoic fluid. Consequently, information has been gained as to the amount of virus liberated into the allantoic fluid as a result of adsorption of one ID_{50} of seed virus (2, 3). The injection of homologous irradiated virus during the constant periods, however, prevented or delayed the appearance of virus in the allantoic fluid either through inhibition of formation or of liberation of virus.

It is obvious that much could be learned about the infectious process if one could follow the course of infection within the allantoic membrane during the time corresponding to the constant periods in the allantoic fluid. It is the aim of this and the subsequent papers of this series to summarize studies on the development of virus activities in the allantoic tissue.

* The work described in this study was supported by a grant-in-aid from the United States Public Health Service.

Materials and Methods

Most of the pertinent technics for the preparation of materials and the experimental procedures have been discussed in previous papers (1, 2). It suffices, therefore, to outline briefly the general procedure of the growth curve experiments to be reported.

An adequate number of 12-day-old chick embryos was injected at t_0 time with 0.2 ml. of suitably diluted allantoic fluid containing either the PR8 strain of influenza A or the Lee strain of influenza B virus. In some experiments or experimental groups, this was the only injection given. In others, a second injection of 0.5 ml. of homologous or heterologous virus inactivated by ultraviolet irradiation was administered one-half hour after the infecting dose. These latter preparations were obtained by sedimenting the virus from allantoic fluid by high speed centrifugation at 20,000 R.P.M. for 20 minutes, and resuspending the sediment in one-eighth volume of the supernatant fluid. The concentrates were dialyzed against 20 volumes of buffered saline solution and irradiated by ultraviolet light for a sufficient length of time, as determined by preliminary tests, to destroy infectivity but to leave the interfering property largely intact (4). As a rule, 0.5 ml. of these preparations diluted at least 1:27 prevented propagation of subsequently injected active virus (about 10^5 ID₅₀) to such an extent as to prevent formation of measurable amounts of hemagglutinins. In earlier experiments, the materials were injected into the allantoic cavity through the air space, in later tests, through holes drilled into the shell at the side of the eggs a few millimeters below the limit of this space, a separate hole being used for each injection. An additional hole was made over the air sac for the relief of pressure. Care was taken to inoculate through areas of chorioallantoic membrane free of blood vessels. After each injection, the corresponding hole was sealed with nail polish. By this technic, flooding of the shell membrane at the air sac end caused by back-flow of fluid through the punctures was avoided, thus preventing the occasional deaths of embryos due to this occurrence. The injections were performed at intervals in order to allow for the harvest of the individual groups of eggs at the precise time planned. The trays of eggs were returned to the incubator immediately after each injection to minimize cooling of the eggs. Harvests were made at hourly intervals, using five to six embryos per group. First, aliquots of the allantoic fluids were removed by needle and syringe and pooled according to groups, then the remainder was poured off and the total volume measured in some of the groups of eggs. Thereafter, the contents of the eggs were discarded except for the allantoic membranes which adhered to the shell. They were washed twice *in situ* with buffered saline solution before removal from the shells, and rinsed twice more with saline solution in Petri dishes. The fluids were kept at 4°C. until titrations could be made. The membranes were kept at -15°C. for a few days. They were thawed usually 1 day prior to the titrations, emulsified in ice cold Waring blenders for 3 minutes, using 5 ml. per membrane of buffered saline solution which contained 100 units of penicillin and 100 µg. of streptomycin per ml. The suspensions were clarified by centrifugation at 2000 R.P.M. for 20 minutes and kept at 4°C. until titrations were made. The titer remained constant at this temperature for at least 1 week. Titrations for infectivity were made as described (1), using five 10- or 11-day-old chick embryos per dilution in case of the experimental preparations, and ten per dilution for the titration of the seed virus. The 50 per cent infectivity end-points were calculated according to Reed and Muench. The values recorded in the figures are expressed as ID₅₀/ml. of allantoic fluid or membrane suspension.

EXPERIMENTAL

The first set of experiments to be presented was devised to assay the virus content of the allantoic membranes following infection with either the PR8 strain of influenza A or the Lee strain of influenza B, respectively. The period

under study corresponded to the constant period, as far as the infectivity of the allantoic fluids was concerned. As can be seen in Fig. 1, the virus titer, in agreement with previous reports (2), remained constant in the allantoic fluids for 6 hours in the case of the PR8 strain, and for 9 hours in that of the Lee virus. On the other hand, titration of the suspensions of allantoic membranes collected from the same eggs at the same time intervals showed that constant levels of activity were encountered only during the first 4 hours with PR8 and for the first 6 hours with the Lee strain. Thereafter, the virus content of the tissues increased rather sharply so that the titer exceeded that of

FIG. 1. Comparison of infectivity of allantoic fluids and membranes in the first 6 and 9 hours after infection with PR8 and Lee virus, respectively.

the corresponding allantoic fluids. Since the average yield of allantoic fluid at this stage of embryonic development amounts to between 8 and 10 ml., whereas the membranes were suspended in only 5 ml. of saline solution, the difference between the total amount of virus found during the constant periods in the allantoic fluids, on the one hand, and in the membranes, on the other, was of the order of log 1.4 to 1.7 in favor of the fluid. This finding emphasized again the previously demonstrated discrepancy between the amount of seed virus found in the tissues and that calculated to be adsorbed (1). The amount of non-adsorbed virus in the allantoic fluid corresponded to about 30 per cent; that found in the tissue, to only about 1 to 2 per cent of the seed, instead of the expected 70 per cent.

The effect of inactivated, interfering virus of the homologous or heterologous type upon the propagation of the active agent in conjunction with the host cells

is shown in Fig. 2. The curves shown represent the combined results of three experiments conducted with the PR8 strain, using approximately 10^4 ID₅₀ for infection. The upper part of the figure records the data obtained with the allantoic fluids which agreed with the observations previously published (2); i.e., a typical one-step growth curve in the case where heterologous irradiated virus was injected subsequent to infection; no release of virus from the infected

FIG. 2. The effect of injection of homologous and heterologous irradiated virus, following infection, upon infectivity curves in allantoic fluids and membranes. The crosses denote mean titers during the constant periods.

cells into the allantoic fluid in case homologous irradiated virus was used; and a somewhat slower rise in infectivity in the controls which, however, continued at an increased rate beyond the period shown in the figure. The titrations of the membranes derived from the embryos not treated with irradiated virus showed a constant period of 4 hours, followed by a sharp rise in activity. The incline of the curve fell off gradually as the time of incubation increased, but it continued to rise after the 10th hour of incubation in one of the experiments carried over a 24 hour period. If heterologous irradiated virus (Lee) was injected one-half hour after infection, the constant period in the membranes extended, likewise, over 4 hours, but the subsequent rise in infectivity was less

steep than that observed in the control curve. The divergence between the two curves became more pronounced as time proceeded, and there was no significant further increase in titer after the 10th hour of incubation. The third curve represents the results of membrane titrations after secondary injection of homologous irradiated virus, and shows that virus production was markedly suppressed. There was no rise in infectivity during the 10 hour period shown in the figure, but, thereafter, in the one experiment extending over 24 hours, a definite rise in titer occurred.

A similar experiment employing 10^4 ID₅₀ of the Lee strain as the infecting agent instead of the PR8 virus gave similar results except for the more prolonged constant periods expected from the data shown in Fig. 1. In other experiments it became apparent that the dose of active virus used was of some importance. Using 10^4 ID₅₀ of PR8 virus, results were obtained which agreed in principle with those reported above with 10^4 ID₅₀, except that suppression of propagation by homologous irradiated virus was less pronounced, and a distinct rise in infectivity became measurable in the membranes about 8 hours after infection. Little effect of the homologous inhibitor was noted when injected subsequent to infection with about 10^3 ID₅₀.

These experiments revealed a number of facts. First, the heterologous irradiated virus, which had been used for the demonstration of one-step growth curves (2, 3), is not without effect upon the propagation of active virus in the tissues of the allantoic sac. The difference in the infectivity curve of this series as compared to that of the controls is not merely the result of the prevention of additional adsorption of virus freshly released from the tissues in the case of the eggs treated with the heterologous irradiated virus. As can be seen in the figure, liberation of new virus into the allantoic fluid became measurable only after the 6th hour of incubation, whereas the difference in the amounts of active virus in the membranes was apparent as soon as the titers began to rise. The irradiated heterologous virus is able then to exert some inhibitory effect upon virus propagation in the cells after infection has taken place.

Second, not all the virus formed in the membrane is released into the allantoic fluid. When heterologous irradiated virus is injected one-half hour after infection, it is assumed that only those cells infected during that first one-half hour produce virus, and that all the other cells are rendered resistant through interference. It might be expected, then, that at the end of the intracellular growth period, the titer of the membrane would decrease, since all the cells have either just liberated virus or are resistant to the uptake of virus. However, as is evident from Fig. 2, this is not the case, but the virus curve levels off gradually and the titer remains constant thereafter. This indicates that some of the produced virus is apparently still attached to the cells of the allantoic membrane.

Finally, the experiment shows that the effect of the homologous irradiated

virus is directed toward a delay in multiplication and, usually, a reduction in the amount of virus produced, and not toward prevention of the release from the cells of virus that might have multiplied, a differentiation which could not be made by considering the data of the allantoic fluid titrations (2). The degree of inhibition depends on the size of the original inoculum of active virus; the smaller the infecting dose, the more pronounced the inhibition.

This third point raised a new question. As had been shown in a previous report (Fig. 9, reference 2), the injection of homologous irradiated virus at increasingly delayed intervals after infection with the active agent decreased successively the degree of inhibition, as measured by the liberation of increasingly larger amounts of virus into the allantoic fluid at the end of the proper constant period. For example, if, in the cited experiment, the homologous inhibitor was injected 1 hour after infection with the active Lee virus, practically no rise in virus titer was noted in the allantoic fluid at the end of the 9 hour constant period. With injection of the inhibitor 2, 3, or 4 hours after infection, the amount of virus released increased gradually, but when given after a 6 hour interval, the resulting curve corresponded to that observed following secondary injection of heterologous irradiated virus. If the titers obtained in the allantoic fluid at 10 or 12 hours after infection with the PR8 or Lee strains, respectively, are plotted against the time after infection, when the injection of homologous irradiated virus was given, the points fall reasonably well on a straight line (Fig. 3) connecting the base, which represents the titer of residual non-adsorbed seed virus, with the top line which represents the titer obtained after injection of heterologous irradiated virus.

Inspection of Fig. 3 shows then that propagation of virus may be interrupted any time up to 3 hours after infection with PR8, and up to slightly more than 4 hours after infection with the Lee strain. The figure also seems to suggest that whatever quantity of virus has been produced up to the time of interruption is liberated after the proper constant period. However, during these same periods, (see the curves presented in Figs. 1 and 2), no increase in active virus is demonstrable in the membranes. These findings seem to indicate that viral production occurs in at least two major stages. Conceivably during the first phase, immature, non-infectious forms or building blocks of virus are produced; this development can be interrupted by the homologous inhibitor within certain time limits. In phase 2, these non-infectious forms or building blocks are converted or combined into fully active virus, and this transformation cannot be interrupted by the homologous inhibitor, so that whatever amount of this immature product has been formed up to the time of interruption is subsequently demonstrable as active virus. The data imply, too, that the first stage of virus formation begins shortly after infection of the cells and is completed by the 4th to 6th hour thereafter, depending on the type of virus used. Fully active virus begins to appear only at the end of the first phase.

DISCUSSION

The studies on the propagation of influenza virus in the allantoic membrane have shown that a certain amount of the active seed virus can be demonstrated in suspensions of the tissue immediately after adsorption of the agent (1). The titer of this virus remains constant for about 4 and 6 hours after infection with the PR8 and Lee strains, respectively. Thereafter, a rapid increase in

FIG. 3. The height of the virus titer in the allantoic fluid 10 to 12 hours after infection with PR8 and Lee virus, respectively, as influenced by subsequent injection of homologous irradiated virus at increasing time intervals.

infectivity is noted; *i. e.*, 2 to 3 hours before release of any virus into the allantoic fluids can be detected. Injection of irradiated heterologous virus subsequent to infection exerts a slight inhibitory effect on virus production in the tissues, whereas homologous virus may entirely prevent or delay this propagation. The slight inhibitory effect of the heterologous irradiated virus may be comparable to the "depressor effect" described by Delbrück (5), who found in studies on interference between serologically unrelated bacterial viruses that the excluded agent may decrease the yield of the infecting virus.

The quantitative aspects of virus production in the influenza virus-chick embryo system have been considered in a previous report (2). Calculations were presented concerning the yield of active virus in allantoic fluid derived from adsorption of one ID₅₀ of seed virus in the first infectious cycle (adsorption-propagation-liberation). This value amounted to about 60 ID₅₀ in the average of five experiments with the PR8 strain, and to about 35 in a similar number of tests with the Lee strain. Corresponding figures were obtained

with other strains of influenza A and B virus (3). These calculations now require some comment.

The degree of adsorption was estimated by subtracting the amount of seed virus left free in the allantoic fluid from the total amount injected. As has been pointed out in the preceding paper of this series (1), only between 1 and 5 per cent of the virus thus calculated to be adsorbed can actually be demonstrated in the allantoic tissue. If this small quantity of active virus were the "infecting agent" and the remainder of the seed "wasted," then the yield of virus per ID_{50} of seed would be 20 to 100 times the amount mentioned above; *i. e.*, 1200 to 6000 ID_{50} in the case of PR8, and 700 to 3500 ID_{50} in the case of Lee virus, quantities which conceivably still could result from the infection of one host cell. However, as will be shown in the subsequent paper of this series (6), a large part of the adsorbed active seed virus remains accessible to the action of neutralizing antibodies injected into the allantoic sac following infection without markedly affecting multiplication of virus in conjunction with the host cells. This indicates strongly, that the active seed virus found in the suspensions of the tissues collected during the constant periods may represent "superficially adsorbed" seed virus, and that the non-demonstrable part of the adsorbed virus is probably the one involved in the process of propagation. If this assumption is correct, the values given for the yield of virus per ID_{50} of seed virus would increase only very slightly.

A second point has to be considered in this connection. The calculations under discussion are based on one-step growth curve experiments in which heterologous irradiated virus was injected subsequent to infection. In case the infected eggs are not treated with irradiated virus, multiplication of the agent proceeds in the tissues at a rapid rate, but the liberated virus will spread to other susceptible cells either by continuity or *via* the allantoic fluid thus largely escaping detection and initiating the second infectious cycle before all the virus produced in the first has been released. It is obvious that no accurate information may be gained under these conditions as to the quantity of virus produced as the result of one infectious cycle. On the other hand, the secondary injection of heterologous irradiated virus inhibits the initiation of a second infectious cycle by preventing extensive adsorption of the liberated virus onto the remaining susceptible host cells and by induction of the interference phenomenon. However, this injection is not without effect upon multiplication of the virus in the first cycle, in that the curve of viral increase in the tissues is definitely lower than that found in controls not treated with heterologous irradiated virus. Thus, the yield of virus per ID_{50} of seed virus is not optimal under these conditions.

The tests with the heterologous irradiated virus also showed that not all of the virus produced is actually released into the allantoic fluid, but that part of it remains attached to the tissues. However, this quantity of virus amounts

to only a fraction of that found in the fluid at the end of the infectious cycle and, therefore, would not alter substantially the calculations discussed.

Although the quantitative aspects of virus multiplication cannot be clarified further at the present time the experiments presented may offer some insight into the mechanism of viral propagation. The data would seem to warrant the assumption that propagation of virus occurs in two major phases. Presumably in the first, non-infectious material is built, production of which is completed at about the end of the second third of the growth period in conjunction with the host tissues. Conversion into fully active virus appears to begin only then. In this regard it is of interest to note that Gard and von Magnus (7) observed in allantoic fluids infected with influenza A virus, which were obtained under certain conditions, a component differing from the fully active virus which they considered a precursor of the virus. The suggested multiphase development of influenza virus would seem to be in agreement with certain observations made in the field of bacterial viruses. By exposure of infected bacteria to radiations and subsequent assay of the remaining "infectious centers," Latarjet (8) has shown that inactivation during the first third of the intracellular growth period proceeds according to single hit curves, but that thereafter, the rate of inactivation corresponds to that of multiple hit curves. This indicates that the increase in virus material begins only in about the second third of the period. It also was found that resistance to ultraviolet and x-radiation becomes increasingly stronger during the second phase of the intracellular period, presumably by the accumulation of newly produced material which adsorbs part of the radiation (9). Chemical analyses reported by Cohen (10) showed that synthesis of virus protein begins in the bacteria immediately after infection, whereas the development of desoxyribosenucleic acid can be detected only after about one-third of the period has elapsed. The curve of nucleic acid production runs parallel to that of active virus content of the bacteria, but precedes it by a definite time interval (11).

SUMMARY

Experiments have been reported on the propagation of influenza viruses in the allantoic membrane of the developing chick embryo during the first infectious cycle.

After adsorption of the seed virus onto the host cells, only a small percentage of it remains demonstrable by infectivity titrations. This amount remains constant for 4 hours in the case of infection with PR8 virus, and for 6 hours in that of infection with Lee virus. Thereafter, a sharp rise in infectivity occurs 2 to 3 hours before liberation of the new generations of active virus into the allantoic fluid can be detected.

Injection of homologous virus, inactivated by ultraviolet irradiation, following infection prevents or delays the production of virus in the tissues,

depending to some extent upon the number of ID_{50} of active virus used as inoculum. The smaller the dose, the more pronounced the inhibitory effect.

With increasing delay in the injection of the inhibitor, progressively more virus is produced and liberated 6 and 9 hours after infection with PR8 and Lee virus, respectively. Thus, production of virus may be interrupted by the homologous inhibitor when given up to 3 hours after infection with PR8, and up to $4\frac{1}{2}$ hours after infection with Lee virus. Since no increase in infectivity can be detected during these 3 and $4\frac{1}{2}$ hour periods in the tissues, it is suggested that influenza virus propagates in at least two major stages: first, non-infectious, immature virus material is produced which, subsequently, is converted into the fully active agent. Presumably the first step can be interrupted by the homologous inhibitor, while the second cannot.

Heterologous irradiated virus, injected after infection of the tissue, exerts only a slight inhibitory effect on the production of virus.

STUDIES ON HOST-VIRUS INTERACTIONS IN THE CHICK EMBRYO-INFLUENZA VIRUS SYSTEM*

III. DEVELOPMENT OF INFECTIVITY, HEMAGGLUTINATION, AND COMPLEMENT FIXATION ACTIVITIES DURING THE FIRST INFECTIOUS CYCLE

BY WERNER HENLE, M.D., AND GERTRUDE HENLE, M.D.

(From The Children's Hospital of Philadelphia (Department of Pediatrics, School of Medicine, University of Pennsylvania), Philadelphia)

(Received for publication, January 4, 1949)

Certain of the experiments reported in the preceding paper suggested that propagation of influenza virus in or on the cells lining the allantoic sac of the chick embryo can be divided into two major phases. According to this suggestion, the first phase would correspond to the production of some incomplete non-infectious forms or building blocks of the virus which, in the second phase, are converted or combined into fully active virus (1). It seemed possible that the material produced in the earlier phase might be endowed with some attributes of influenza virus other than infectivity. Consequently, attempts were made to study the development of hemagglutinins and of complement-fixing antigens. In order to be able to measure these properties during the early period after infection, *i. e.* during the first cycle, it was necessary to employ infective doses in the order of 10^9 ID₅₀ of active virus.

It has been found in previous experiments that the selection of the seed is of prime importance (2). If the inocula were prepared under adverse conditions such as permitted the accumulation of inactive virus in the allantoic fluids, passage of these without dilution was found to result in partial interference with the propagation of the active virus by the non-infective material. On the other hand, if the allantoic fluids intended for seed were harvested when the infectivity just reached its peak, or shortly before that time, they could be used undiluted for passage to new chick embryos without the apparent intervention of interference. It is obvious that the present study required seed prepared under the latter conditions.

The experiments to be reported in this paper were conducted exclusively with the PR8 strain of influenza A virus. They show that production of both the virus (600S) and soluble (30S) complement fixation antigens (3) in the tissues can be demonstrated prior to the development of hemagglutinins which, in turn, precede the increase in infectivity. It will also be shown that the titer of hemagglutinins may increase in the allantoic fluid without a concomitant rise in infectivity and that under certain conditions suspensions of allantoic mem-

* The work described in this paper has been supported by a grant-in-aid from the United States Public Health Service.

brane may show marked titers of infectivity without showing a corresponding increase in development of hemagglutinins.

Methods and Materials

Seed was prepared by injecting 10-day-old chick embryos with 0.2 ml. of allantoic fluid containing the PR8 strain of influenza A diluted in broth to 10^{-7} . After incubation of the eggs for 48 hours at $36-37^{\circ}\text{C}$., they were chilled and the allantoic fluids harvested aseptically. The seed thus obtained was stored at 4°C . for not more than 5 days before use. These allantoic fluids contained between $10^{9.73}$ and $10^{10.30}$ ID₅₀ per ml. at the day of the experiment, and agglutinated chicken red cells in dilution 1:2048 to 1:8192.

The technics used for the growth experiments and the methods employed for the preparation of inactive, interfering virus have been described in detail in the preceding papers (1, 4). In some of the experiments of the present studies, immune serum was injected subsequent to infection of the eggs. The sera were prepared as follows, according to the technic described by Hudson, Sigel, and Markham (5). Infectious allantoic fluid was injected intramuscularly (1 ml.) and intraabdominally (3 ml.) into adult chickens. They were bled 10 to 14 days later and the sera tested for their ability to inhibit hemagglutination. Those sera which in dilution 1:64 neutralized 256 or more units of hemagglutinin of PR8 or Lee virus, respectively, were pooled and used for the tests. They were injected allantoically in 0.2 ml. amounts either undiluted or diluted, 1:10, in buffered saline solution.

The methods employed for the assay of infectivity have been published (1, 4). Hemagglutination was measured by the pattern test. To 0.4 ml. of each of the serial twofold dilutions of the allantoic fluids or membrane suspensions, 0.2 ml. of a 1 per cent suspension of washed, fresh chicken erythrocytes was added. After shaking, the tubes were incubated at 4°C . until the red cells had settled, and the degree of agglutination was read according to the pattern formed at the bottom of the tubes (6). The initial dilution of the test material giving the last definitely positive reading (\pm) was taken as the end-point. In many instances, the hemagglutination test was run in duplicate or repeated a second time. In these cases, the average values were computed for inclusion in the figures and tables. With certain of the preparations, the test tubes were shaken and read again after settling of the red cells.

The complement fixation technic employed has been fully described (3). When a concentrated preparation of the virus or 600S antigens was desired, the allantoic fluids or the suspensions of allantoic membranes were subjected to high speed centrifugation at 20,000 R.P.M. for 20 minutes, and the sediments were resuspended in a small volume of buffered saline solution to effect an 8- to 16-fold concentration of the antigen. The supernatant fluids were tested for the presence of 30S or soluble antigen. No attempts were made to concentrate this fraction. To differentiate further between the two antigenically distinct fractions, two types of sera were employed in all tests: a human influenza A convalescent serum containing high levels of antibodies against both the virus and soluble antigens, and a human postvaccination serum which reacted with the virus but not with the soluble antigen. The last initial dilution of the preparations giving complete fixation of complement in the presence of antibody was considered as the end-point. Influenza B convalescent sera were used for control purposes.

EXPERIMENTAL

Divergence in the Titers of Infectivity, Hemagglutination, and Complement-Fixing Activity

In the first experiment to be reported, 12-day-old chick embryos were infected with 0.2 ml. of undiluted infectious allantoic fluid containing $10^{9.6}$ ID₅₀ of PR8

virus. The allantoic fluids and membranes from groups of six eggs each were harvested at hourly intervals beginning 1 hour after infection, and tested for infectivity, hemagglutinating capacity, and complement-fixing activity in the presence of specific human sera. The results are recorded in Fig. 1. On the left side are shown the data of the allantoic fluid series, on the right those obtained with the membrane preparations. In the allantoic fluid series, the constant period of infectivity amounted to 6 hours. Thereafter, the virus titer began to rise slowly. The allantoic fluids of eggs incubated for 10 to 24 hours yielded infectivity levels in excess of $10^{9.3}$ ID₅₀ per ml., which indicated that the seed did not contain significant amounts of interfering agents (2).

FIG. 1. The development of infectivity, hemagglutinating, and complement-fixing activities in allantoic fluids and membranes following infection with $10^{9.6}$ ID₅₀ of active virus.

ID₅₀ = 50 per cent infectivity doses per ml. Hem = hemagglutinin titer. CFV = complement-fixing titer of virus antigen; conc. = after eightfold concentration. CFS = complement-fixing titer of soluble antigen.

Hemagglutination tests with the same fluids showed that in agreement with earlier observations (7), some of the injected hemagglutinins remained unadsorbed, yielding a titer of about 1:12. The constant period before hemagglutination was observed to increase extended over 3 hours only, in contrast to the 6 hours before a rise in infectivity occurred. Following the 3 hour constant period, a slight but definite increase had occurred by the 4th hour, as determined by duplicate and repeat tests, and in the next 2 hours, the titer rose about 40-fold, whereas the infectivity remained unaltered. This unexpected result requires further study. At present, only this much may be said: The early increase of the hemagglutinins in the allantoic fluid requires both the living

host and fully active virus, since neither the injection into living chick embryos of similar amounts of virus inactivated by ultraviolet irradiation, nor the inoculation of comparable concentrations of active virus into eggs which had been killed just prior to the test by intravenous injection of small amounts of normal allantoic fluid, led to a change in the titer of the non-adsorbed hemagglutinins during a 24 hour period of incubation.

The complement fixation tests with the straight allantoic fluids as antigens became positive after 6 hours. However, upon concentration by high speed centrifugation, a rise in the antigen titer (600S or virus antigen) became ap-

† Contains antibodies against the virus and soluble or 30S antigens.

parent at 4 hours concurrently with the development of hemagglutinins. The supernatant fluids were uniformly negative. Thus, no soluble or 30S antigen became demonstrable in the allantoic fluids during the period under test. Results of these titrations are included in Table I.

Tests with the suspensions of allantoic membranes are shown in the right-hand section of Fig. 1. The infectivity showed a constant period of 5 hours instead of the usual 4, as observed with more dilute inocula of virus (1). The titer rose sharply by the 6th hour, but only a slight additional increase was noted thereafter. The hemagglutination tests remained negative for 3 hours.

The 4 hour suspension gave irregular patterns of agglutination in the initial reading of the test. Upon shaking up of the test tubes and resettling of the cells, the titer increased somewhat and the usual patterns were observed. The titers continued to rise in the ensuing hours, although at a gradually decreasing rate.

The complement fixation test with the membrane preparations remained negative in the first 2 hours; in the 3rd hour it became positive, and increased in strength up to the 5th hour. No significant rise in titer was recorded thereafter. Both the virus and soluble antigens developed simultaneously, as shown in detail in Table I. Concentration of the virus antigen by high speed centrifugation increased the titer approximately eightfold, but did not lead to an earlier demonstration of antigen in contrast to the findings in the allantoic fluid.

This experiment showed the divergence between development of infectivity and hemagglutinating property, since the ratio between the infectivity and hemagglutinin titers changes during the experimental period. The number of ID_{50} corresponding to 1 hemagglutinating unit for the various preparations of both the allantoic fluids and the membranes in the first 3 hours after infection amounts to about 10^7 , but it subsequently decreases to about 10^5 ID_{50} by the 6th hour.

All test employing undiluted allantoic fluid, *i.e.* between $10^{9.0}$ and $10^{9.6}$ ID_{50} per dose, gave, in general, the same results as those recorded in Fig. 1. The periods elapsing before any changes in the various reactivities became measurable have been recorded in Table II. It is obvious that with the complexity of the experimental procedures and the technics used, minor variations may be expected. However, in two instances, the discrepancies appeared more pronounced. The constant period of infectivity in the membranes of Experiment 2 extended only over 3 hours. No explanation can be given for this exceptional result. The other irregularity concerns the complement fixation tests in Experiment 4, with concentrated allantoic fluid antigens which remained negative for 5 hours instead of 3. However, as can be seen in the membrane preparations of the same series, the appearance of both positive hemagglutination and complement fixation reactions was likewise somewhat delayed.

Dilution of the seed virus in tenfold steps led to the results shown in Fig. 2. This figure represents the results of several experiments employing each of the individual dilutions. As far as the allantoic fluid series are concerned, the infectivity showed constant periods of 5 to 6 hours, varying in the individual tests within this range. The levels obtained during the constant periods were spaced apart in conformity with the dilution of the seed. Hemagglutinins increased measurably during the experimental period only in those groups of eggs injected with undiluted or tenfold diluted seed virus. In each instance, the increase was noted before the infectivity commenced to rise. Finally,

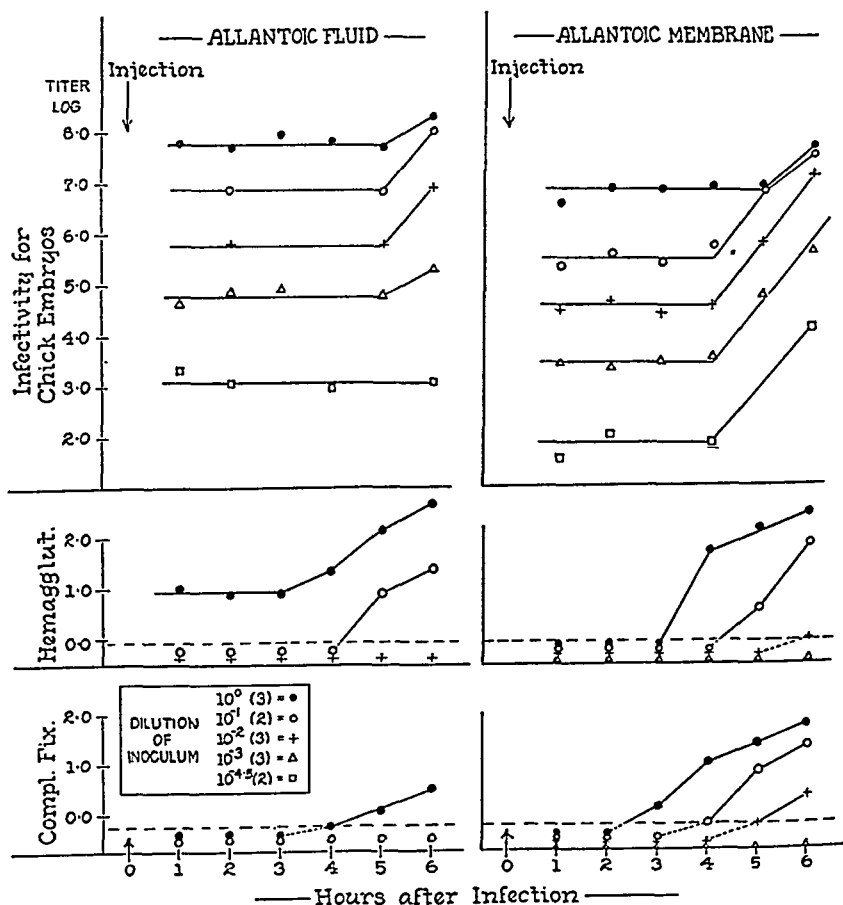

FIG. 2. The effect of dilution of the seed virus upon development of the various properties of influenza virus in allantoic fluids and membranes.

complement fixation antigen became demonstrable under these conditions only when undiluted seed was employed.

The results of infectivity titrations with the suspensions of allantoic membranes showed that after injection of undiluted seed, a constant period of 5 hours was observed. If one-tenth or less than that amount was injected, it extended regularly over 4 hours. After the constant period, the titer rose to similar heights in 6 hours in the case of the 10^0 and 10^{-1} inocula, and the results in the 10^{-2} series approached that level. However, when the seed was diluted further, the resulting curves ran roughly parallel. In the hemagglutination tests, positive results were obtained during the experimental period of 6 hours only when undiluted seed or 10- and 100-fold dilutions thereof were injected. The test became positive at the 4th, 5th, and 6th hours, in the order of the decreasing dilutions used for the inoculation. The titer obtained at the end of the experimental period with the 10^{-1} inoculum did not quite reach the level observed in the tests with undiluted seed, as was the case in the infectivity titrations. The development of positive complement fixation reactions with centrifugally concentrated materials (virus antigen), likewise, showed spacing at hourly intervals according to the dilution of seed virus used. However, the test regularly became positive 1 hour prior to the hemagglutination reaction. Again, the titers obtained in 5 to 6 hours following injection of 10^0 or 10^{-1} dilutions of the seed were not identical, but the difference noted was less than that which might have been expected, considering the dilution factor of the seed. With seed diluted more than 100-fold, only the infectivity remained measurable, whereas the other properties no longer reached detectable levels of activity during the experimental period.

These observations seem to indicate that the 10^{-1} inoculum, or about 10^1 ID₅₀, causes infection of all the susceptible cells, since ten times the dose of seed virus does not increase the yield of virus in the membranes. The data of the hemagglutination and complement fixation tests, on the other hand, are not quite in agreement with this conclusion. However, discrepancies between the infectivity and the other properties studied have been noted also in the allantoic fluid series, as outlined above, which indicate a certain independence of the various activities of each other.

The Effect of Homologous and Heterologous Irradiated Virus upon the Growth Curves

As has been pointed out in the preceding publication (1), a secondary injection of virus inactivated by ultraviolet irradiation following the infection of the eggs produced marked inhibition of propagation of virus in the tissues in case the homologous irradiated agent was used, and only a relatively slight effect in the case of the heterologous type. The inhibition by homologous irradiated virus was the more pronounced, the smaller the dose of active virus used for infection. On the other hand, when about 10^9 ID₅₀ of active virus was used for

infection, the secondary injection of homologous inhibitor failed to produce a distinct inhibitory effect; the constant period was only slightly prolonged, and the infectivity levels reached were of the order of those attained in the groups of eggs treated with the heterologous irradiated agent. The results of hemagglutination and complement fixation tests at this level of infecting dose, likewise, were closely similar, regardless of whether homologous or heterologous irradiated virus was injected following infection. They were slightly inferior to the levels obtained in the control groups not treated with irradiated virus.

The Effect of Immune Serum upon the Growth Curves

It is generally accepted that antibody cannot reach virus particles harbored by the host cells. In the type of experiments reported here, it was considered possible that immune serum injected into the allantoic cavity of the infected eggs would neutralize a large part of the non-adsorbed seed virus, and also part of any seed virus that might be superficially adsorbed onto the membranes and not be participating in propagation.

In preliminary experiments, it was established that antibodies against influenza virus are not adsorbed onto the membranes of normal chick embryos, nor are they resorbed into the blood stream to a measurable extent during experimental periods extending over 6 to 8 hours. When normal eggs were injected by the allantoic route with immune serum, and the membranes harvested by the usual technic several hours later, it could be shown that the resulting tissue suspensions were devoid of any neutralizing activity as far as infectivity was concerned, and inhibition of hemagglutination did not exceed that exerted by suspension of normal membranes.

Injection of anti-PR8 sera into eggs one-half hour following infection with about 10^9 ID₅₀ of PR8 virus failed to neutralize all the free, non-adsorbed virus in the allantoic fluid, even when 0.2 ml. of undiluted serum was employed. As seen in Fig. 3, which summarizes the composite results of four experiments of this kind, the infectivity decreased by more than 99 per cent, and only a slight rise was noted in the 6th hour of incubation. The hemagglutination and complement fixation reactions remained negative throughout the experimental period.

The tests with the allantoic membranes showed a decrease in infectivity to approximately 0.1 per cent of that of the controls in the first 3 hours. The titer then increased very sharply, and by the 5th hour, matched the levels noted in the groups not treated with serum. Thus, evidence has been obtained that a large part of the adsorbed seed virus can be neutralized without affecting significantly the ultimate yield of virus in the tissues. With regard to the hemagglutination tests, the serum prevented apparently the development of this activity from reaching detectable levels in the membranes during the entire period under study, in spite of the fact that the infectivity titers in both

groups attained similar heights at the end of the 6 hour incubation. High speed centrifugation of these materials and resuspension of the sediments in one-eighth of the original volume, likewise, failed to reveal hemagglutinins. No explanation can be given at present for this paradoxical finding. As to the complement fixation tests, only the 600S or virus-antigen was measured in these series after concentration by high speed centrifugation. It developed in gradually increasing amounts, but its appearance was somewhat delayed and the titers were reduced as compared with the controls. If one-tenth the amount of

FIG. 3. The effect of injection of homologous antisera subsequent to infection with about 10^3 ID₅₀ upon the development of the various properties of influenza virus in allantoic fluids and membranes.

homologous immune serum was injected following infection, the general appearance of the growth curves in the tissues was similar to that described for the tests with undiluted serum, except for the fact that under these conditions, small amounts of hemagglutinin became demonstrable at the end of the 6 hour incubation period. Using undiluted anti-Lee instead of anti-PR8 serum, the results resembled those of the control series except for slight reductions in the various activities in the allantoic fluids, caused most likely by non-specific

inhibitors present in the serum (8). The allantoic membrane titrations were not affected by this property of the serum.

Similar experiments were conducted with more dilute seed and undiluted homologous immune serum. The essential results are recorded in Fig. 4. In this figure, the infectivity titers obtained during the constant periods in the allantoic fluids and membranes with and without secondary administration of serum are plotted according to the dilution of seed virus used for the primary injection. It also includes a comparison of the results recorded with membranes at the end of the experimental period (6 to 8 hours after infection).

FIG. 4. The effect of homologous immune serum upon the amount of virus in chick embryos infected with decreasing amounts of virus as measured: (a) in the allantoic fluid, (b) the allantoic membrane during the constant periods, and (c) in the tissue at the end of the experimental period.

It can be seen that in the allantoic fluids, injection of serum resulted in a similar rate of reduction in infectivity when undiluted or tenfold diluted seed virus was injected. With further dilution of the inoculum, most or all of the virus activity was neutralized.

The reduction of infectivity in the membrane during the constant period, which never was less than 3 hours, proceeded at a similar rate, regardless of the dilution of the seed. This difference in the neutralization of free and adsorbed virus may be comparable to the difference between the rates of adsorption of virus onto the allantoic sac and onto red cells, which has been discussed in a preceding paper (4). The non-adsorbed virus and the antibodies are intermixed in the same menstium, allantoic fluid, and therefore, the chances of their

colliding are greater, whereas neutralization of the adsorbed virus can take place only at the fluid-tissue interface.

Inspection of the data obtained with membranes at the end of the experimental period shows that only in the case of undiluted seed, both control and serum groups reached similar levels of infectivity; *i.e.*, the virus grew out to the same extent in conjunction with the host cells in both series. With tenfold dilution of the seed, only a slight reduction was noted, but on further decrease in the dose (10^{-2} or less), the titers attained in the serum groups amounted to less than 1 per cent of those encountered in the controls. Essentially similar results were obtained if one-tenth of the amount of serum were used in these experiments. However, only with dilution of the seed to 10^{-3} or less, was all of the non-adsorbed virus neutralized in the allantoic fluid.

DISCUSSION

Studies on the propagation of influenza virus in the allantoic membrane, using large doses of seed virus, require particular precautions. It has been shown in the past that, under certain conditions, apparently enough inactive virus may accumulate in the allantoic fluids of the infected eggs to cause interference with the multiplication of the active virus on passage (2). For example, if eggs are seeded with large amounts of virus and permitted to incubate for extended periods of time, or if the harvested allantoic fluids are stored under adverse conditions, or frozen and thawed repeatedly, one finds that upon subculture in eggs dilute seed will produce a larger yield of virus than a more concentrated inoculum. The conditions can be reproduced by partially inactivating optimally grown seed by ultraviolet irradiation. On the other hand, if allantoic fluid is harvested at the time the infectivity has just reached its peak, *i. e.* 48 hours after inoculation of seed diluted to 10^{-5} to 10^{-7} , for instance, then passage of the undiluted allantoic fluid will result in infectivity titers equal to those obtained in subcultures of dilute seed.

Subsequent studies by von Magnus (9) have shown that factors other than inactivation of virus may play a role in the interfering activity of certain seeds. Serial passage of undiluted allantoic fluid at 18 to 24 hour intervals, starting with optimally produced seed, will lead after two to three transfers to inferior results, comparable to those described in the above paragraph. Although this type of experiment does not exclude the possibility of inactivation of some of the non-adsorbed seed virus during the incubation period, interpretation of the data is complicated by the demonstration in such allantoic fluids of particles smaller in size than the active virus, which apparently are endowed with hemagglutinating, and possibly interfering activities (10). It has been suggested that these particles constitute "precursors" of the virus.

In the preceding paper (1), indirect evidence has been presented which may be taken to indicate that the formation of virus occurs in at least two phases;

possibly during the first, apparently non-infectious, immature forms or building blocks of virus are produced which, in the second phase, are converted or combined into fully active virus. The data recorded in the present study seem to afford more direct evidence for this suggestion.

The growth curve experiments with suspensions of allantoic membranes, using 10^9 ID₅₀ of virus as inoculum, show that the various properties of influenza virus become detectable or reveal increments in the following order: The complement-fixing activity against both the virus or 600S and the soluble or 30S antigens reaches measurable levels in 3 hours, the hemagglutinating capacity in 4 hours, and infectivity begins to increase in 5 to 6 hours. Concentration of the active materials by high speed centrifugation fails to change the time relationships: there still remain 2 hours during which no record can be obtained concerning the activities of the virus in the tissues. It must be emphasized, however, that both the complement fixation and the hemmagglutination reactions require accumulation of relatively large quantities of the active materials before they become measurable. These experiments indicate then that the hypothetical "immature forms" or building blocks of the virus are already endowed with complement-fixing and hemagglutinating activities.¹

Similar differences between the infectivity, on the one hand, and the hemagglutinating and complement-fixing capacities, on the other, are noted in the curves obtained with the allantoic fluids. A distinct rise in hemagglutinins accompanied by complement-fixing activity occurs regularly 4 hours after infection; *i.e.*, 1 to 2 hours before any changes in infectivity become apparent. Although there is no proof that the data obtained with the membranes and fluids are based upon the same basic phenomenon, it seems likely that they are.

The non-infectious hemagglutinating and complement-fixing materials are considered, at present, as immature virus particles. However, the available evidence is insufficient, as yet, to regard this problem as closed. The experiments presented by Gard and von Magnus (10), and those recorded in the preceding paper (1) favor the explanation just outlined, but the possibility that this material derives from the injected seed virus has not been definitely refuted. It is improbable that the early increase in hemagglutinins in the allantoic fluids is caused by elution or breakdown of the seed virus, since in either case there should be concurrent changes in the infectivity. Furthermore, only injection of fully active virus produces these results, whereas injection of irradiated virus, in which the elution mechanism apparently is unaltered (11), does not lead to changes in the titer of residual non-adsorbed hemagglutinins (7). On the other hand, the fact that injection of immune serum after infection appears to prevent early formation of hemagglutinins in the membranes in spite of the development of infectivity titers comparable to those of the controls not treated with

¹ Recent experiments indicated that the interfering capacity of these fluids after dialysis and ultraviolet irradiation increased simultaneously with the hemagglutinins.

serum, may be taken as support for the second alternative. However, these latter data may be based on other principles, possibly of a serological nature which will be discussed further below.

Another point concerning the constant period of infectivity in the tissue requires discussion. It has been suggested that some of the seed virus is "superficially adsorbed" onto the tissue; *i.e.*, it probably is not participating in the propagative process (4). Indeed, much of the adsorbed seed virus remains accessible to the action of neutralizing antibody. Injection of specific immune sera following infection reduces the infectivity of the membranes by a factor of about 1000 and shortens the constant periods, but never to less than 3 hours. The "superficially adsorbed" virus sets a base line beyond which propagation of the "infecting virus" must proceed in order to become demonstrable as an increment in titer. The presented evidence suggests that with an inoculum of 10^8 ID₅₀ of active virus, the maximal number of host cells becomes infected, since with larger doses the ultimate yield of virus in the tissue at the end of the experimental period does not increase. Thus, the base line in the case of an inoculum of 10^9 ID₅₀ is approximately tenfold higher and, as a result, the constant period extends over 5 hours instead of 4.

The use of immune serum in these experiments has possible disadvantages. It is conceivable that multivalent antibodies attached to what is considered superficially adsorbed virus may retain free specific antibody groupings if the amount of seed virus is insufficient for their saturation. Upon emulsification of the tissues, these free groupings may then interact with some of the virus thus liberated which was previously inaccessible to the antibodies. Indeed, the increasing difference in the infectivity titers of the membranes in the control and serum groups at the end of the first cycle with the decrease in the amount of seed virus used for infection strongly suggests that such a carry-over of antibody activity may occur. The presented data offer then only a qualitative answer, namely, that some of the seed virus is superficially adsorbed onto the tissue, but they do not reflect what quantity of the seed virus found in membrane suspensions during the constant period falls into that category. Furthermore, it remains to be investigated whether the phenomenon of partial reactivation of neutral virus-antibody mixtures by dilution, as described by Taylor (12), may not affect the interpretation of some of the recorded data since the materials were highly diluted for the infectivity titration and by injection in the allantoic cavity. A difference between the reactivation of the infective and hemagglutinating properties could conceivably contribute toward an explanation of the paradoxical finding of a high increase in infectivity in the apparent absence of development of hemagglutinins in the tissue when immune serum is injected into the allantoic cavity after infection. From these various considerations it is obvious that the recorded experiments have established certain facts, but their explanation must await further experimentation.

SUMMARY

In agreement with earlier observations the infectivity titer in the allantoic fluids of chick embryos injected with influenza A virus remains constant for 5 to 6 hours before an increase in this activity can be noted. In contrast, the titers of hemagglutinin and complement-fixing antigen (virus antigen) have already begun to rise after 3 hours. The origin of the hemagglutinating and complement-fixing but non-infectious material is still obscure.

In the allantoic membrane development of both the soluble and virus antigens can be demonstrated after the 2nd hour of incubation and 1 hour prior to an increase in hemagglutinins and 2 hours prior to a rise in infectivity. Thus there remain the first 2 hours during which no record of virus activity in the tissues can be obtained.

Similar relationships are noted on dilution of the seed both in the allantoic fluids and membranes as long as the various properties reach measurable levels during the experimental period of one infectious cycle.

Injection of high titered immune serum following infection with about 10^9 ID₅₀ reduces the amount of demonstrable seed virus in the allantoic fluid and membrane without significantly affecting propagation of the agent in the tissues as measured by infectivity titrations. The production of hemagglutinins appears markedly reduced under these conditions whereas formation of complement-fixing antigen is only slightly delayed and decreased.

No definite explanations for the various discrepancies between the infectivity and hemagglutination can be given at present.

Note Added to Proof.—In a recent paper which was received only after submission of the three foregoing manuscripts for publication, Hoyle (13) reported several observations in agreement with some of those recorded in the present studies. He was unable to detect more than 1 per cent of the adsorbed seed virus in the tissues of the allantoic sac of chick embryos as measured by hemagglutination and infectivity tests (see Paper I of this series (4)), and demonstrated that the development of one of the complement-fixing antigens, the soluble antigen, preceded the formation of hemagglutinin in the allantoic membrane, a point discussed, among others, in the above paper.

OBSERVATIONS ON THE RELEASE OF SERUM FIBRINOLYSIN BY SPECIFIC ANTIGEN, PEPTONE, AND CERTAIN POLYSACCHARIDES*

BY GEORGES UNGAR, M.D., AND SHIRLEY H. MIST, Ph.D.

(From the Rheumatic Fever Research Institute, Northwestern University Medical School, Chicago)

(Received for publication, March 11, 1949)

It has been known since 1893 that blood contains a proteolytic enzyme (1) and an inhibitor of this enzyme (2). Failure to detect any proteolytic activity in fresh serum was explained by the assumption that the enzyme was kept neutralized by an excess of the inhibitor. Such a protease-antiprotease system has attracted a great deal of attention because of the possibility that it is associated with certain immunological processes. Recent investigations have indicated that a proteolytic enzyme is present in serum as an inactive precursor which can be activated under certain circumstances. Such activation occurs when serum is treated with chloroform (3) or with a substance produced by certain strains of hemolytic streptococci (4). However, this does not explain the mechanism of fibrinolysis observed under various experimental (5) and clinical (6-8) conditions.

The present paper deals with a new set of conditions in which proteolytic enzymes can be activated in guinea pig serum. The observations reported below would seem to reopen the question of the part played by proteolysis in the mechanism of anaphylactic reactions and possibly other pathological conditions. These observations may bring into agreement early theories of anaphylaxis with recent findings by indicating an explanation for the mechanism of "anaphylatoxin" and "serotoxin" formation and by establishing this mechanism as an important link in the chain of reactions leading to the release of histamine and other toxic substances.

Methods

Several, often confusing nomenclatures are currently used in the study of blood proteases. The terminology proposed by Loomis, George, and Ryder (9) will be employed throughout this paper.

(a) *Preparation of the Enzyme.*—In previous experiments (10) direct estimation of fibrinolysin in sera treated with the specific antigen or peptone gave negative results. Under these conditions, there was good reason to believe that the enzyme, if released, would be neutralized by antifibrinolysin. However, it seemed that fibrinolysin could probably be detected if its combination with antifibrinolysin were prevented. After various unsuccessful attempts to

* This work was supported by a research grant from the United States Public Health Service at the Rheumatic Fever Research Institute, Northwestern University, Chicago.

The tube containing the lowest concentration of enzyme which fails to clot in 30 minutes contains by definition one unit of enzyme. In a previous publication (10) the unit was defined by the same duration of contact and at the same concentration of the reagents but the total volume was 5 ml. For purposes of comparison, all readings obtained in the present experiments have been divided by 12.5.

Some of the results of the fibrinogenolytic technique were confirmed by a viscosimetric method. This was considered more suitable than turbidity measurements used by Grob (12) and Ratnoff (13) because high turbidity of crude enzyme preparations interferes with the accurate reading of results. Two ml. of a 3 per cent solution of gelatin (in saline buffered to

FIG. 2. Titration curve of fibrinolysin by the viscosimetric method. Abscissa, units of fibrinolysin; ordinate, decrease in viscosity of a 3 per cent solution of gelatin in 20 minutes' incubation with fibrinolysin (log scale). Temperature, 37.5°C., pH 7.4.

pH 7.4) is pipetted into an Ostwald viscosimeter kept at 37.5°C. The enzyme solution, filtered and warmed to the same temperature, is made up to the volume of 1.5 ml. and added to the substrate. Flow times are measured five or six times during the first 25 minutes and relative viscosities are plotted against time. The decrease in viscosity is linear for the first 20 minutes

and the initial viscosity can be read by extrapolation. Viscosity change is calculated (in percentage of the total amount) by means of the formula $X \approx 100 \frac{RV_0 - RV_{20}}{RV_0 - 1}$, where RV_0 = initial relative viscosity and RV_{20} = relative viscosity after 20 minutes' digestion. Fig. 2 shows that $\log X$ is linearly related to the logarithm of enzyme concentration for values of X between 2.5 and 25. The calibration curve was obtained with purified fibrinolysin. The results obtained by viscosimetry are also expressed in terms of the units defined above.

RESULTS

The hypothesis tested in the first series of experiments was that failure to detect fibrinolytic activity on addition of the specific antigen or peptone (10) to serum was due to the neutralization of the activated enzyme by antifibrinolysin. If this hypothesis proved true, neutralization should be prevented by precipitating the enzyme shortly after addition of the activating agent. Under these conditions enzyme activity could be detected in the euglobulin precipitate. The findings confirmed this hypothesis.

1. *Anaphylaxis*.—Eight guinea pigs received one subcutaneous injection each of 10 mg. egg albumin.⁴ Twenty-five days after sensitization 1.5 ml. of blood

TABLE I

	0.08	0.08
	0.2	0.4

Data obtained by fibrinogenolytic method.

* 0.1 mg. egg albumin per ml. serum.

was collected from each guinea pig by heart puncture. To each serum specimen 0.1 mg. per ml. egg albumin was added and after 3 minutes' contact, euglobulin was precipitated as described above. The precipitate was redissolved and fibrinolysin activity estimated by the fibrinogenolytic method. The results, summarized in Table I, show that the mean proteolytic activity of sera from sensitized guinea pigs treated with antigen was 1.9 units per ml. (± 0.3); whereas the same sera, untreated, gave the average value of less than 0.3 unit. When serum from normal, non-sensitized guinea pigs was mixed with egg albumin, there was no significant difference between albumin and saline-treated samples (0.19 and 0.14 respectively). These findings indicate

⁴ Soluble egg albumin Merck.

that the antigen-antibody reaction is accompanied by the conversion of inactive profibrinolysin into an active proteolytic enzyme.

2. *Peptone*.—The same results were observed when peptone⁴ was added *in vitro* to normal guinea pig serum. As seen in Table II, the optimum amount of peptone is 20 mg. per ml. of serum. It is also seen that activity varies according to the interval between addition of peptone to serum and precipitation of euglobulin. Activity increases between 25 seconds and 1 minute and then decreases between 2 and 15 minutes. This suggests that the profibrinolysin activation is comparatively rapid and also that simultaneously with the acti-

Fibrinogenolytic method, except when marked (V).

vation the enzyme combines with antifibrinolysin. After the first 1 or 2 minutes the rate of combination is faster than the activation which results in the gradual decrease of free enzyme.

The results shown in Table II were obtained in pooled guinea pig serum. Experiments were also performed on samples from individual guinea pigs and Table III shows the variation in profibrinolysin activation observed in eight guinea pigs. When peptone was applied under optimum conditions of 20 mg. per ml. serum for 2 minutes, the average value of fibrinolysin released is 4.95 units per ml. (± 0.94). The variation, as estimated by the coefficient of variation, is 48.8 in anaphylaxis and 53.2 in the case of peptone.

⁴ Proteose-peptone Difco

Deaths

George Edward Follansbee * for many years chairman of the Judicial Council of the American Medical Association, died in Cleveland, January 1.

Dr. Follansbee was born in Cleveland Oct. 16, 1871. He graduated at Western Reserve University School of Medicine in 1895. His career showed throughout his love for service to medical organization. His local interests included service as staff member at the St. Alexis Hospital and membership in the Academy of Medicine of Cleveland. For many years he had served the academy as a trustee and in other capacities, becoming president in 1918. In 1940 he was awarded honorary membership in recognition of his long service to the academy and to the medical profession. In 1944 the academy acknowledged his many years of service by awarding him its Distinguished Service Medal, the citation stating that he had done as much as any living physician to bring the academy to its position of importance and influence. A former fellow of the American College of Surgeons, Dr. Follansbee is also a specialist certified by the American Board of Surgery. He was president of the Ohio State Medical Association in 1925 and of the Cleveland Medical Library Association in 1931. Representing the Ohio State Medical Association, Dr. Follansbee was a member of the House of Delegates of the American Medical Association from 1919 to 1922 and from 1924 to 1930. He was appointed a member of the Judicial Council of the Association in 1925, again in 1930, in 1935 and again in 1940. In 1944 Dr. Follansbee resigned his chairmanship of the Council which he had held since 1928. He had served with the Committee on the Costs of Medical Care, first as a member representing private practice and later as a member of the executive committee.

In the death of Dr. Follansbee the American Medical Association loses a loyal friend and counselor, whose every act and decision were guided by his respect for the highest ideals and ethics of traditional medicine.

Estes Nichols * Portland, Maine; University of Vermont College of Medicine, Burlington, 1900; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the American Clinical and Climatological Association, American Heart Association, American Public Health Association, American Trudeau Society, International Tuberculosis Association and the American Academy of Tuberculosis Physicians; served as a member of the board of directors of the National Tuberculosis Association; a director and vice president of the Maine Public Health Association; a director of the Cumberland County Public Health Association; served during the Spanish-American War and World War I; colonel, medical reserve corps, U. S. Army, not on active duty; formerly associated with the U. S. Public Health Service; a member of the honorary staff of the Maine General Hospital and consultant to the Maine Eye and Ear Infirmary, Children's Hospital and the U. S. Marine Hospital; for many years medical superintendent of the Maine State Sanatorium, Hebron; died December 12, aged 70.

Mortimer Warren * Portland, Maine; Johns Hopkins University School of Medicine, Baltimore, 1900; assistant clinical pathologist at the Cornell University Medical College, New York, from 1902 to 1910; specialist certified by the American Board of Pathology, Inc.; member of the American Society of Clinical Pathologists, New England Cancer Society and the New England Pathological Society; fellow of the American College of Physicians; chairman of the cancer com-

mittee of the Maine Medical Association; formerly associate with the U. S. Public Health Service; served in the medical corps of the U. S. Army during World War I; special commissioner for infantile paralysis control, Maine, from 1930 to 1932; pathologist at the Roosevelt Hospital, New York, from 1910 to 1916; pathologist at the Maine Eye and Ear Infirmary and since 1922 at the Maine General Hospital; received the honorary doctor of science degree from Bowdoin College in 1931; died at his home in Cape Elizabeth October 8, aged 70 of heart disease.

Elijah White Titus * Washington, D. C.; George Washington University School of Medicine, Washington, 1910; also a pharmacist; clinical professor of obstetrics and gynecology at his alma mater; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; fellow of the American College of Surgeons; member of the Washington Gynecological and Obstetrical Society, Hippocrates Galen Medical Society and the George Washington University Medical Society, of which he had been president; in 1941 honored by the General Alumni Association of George Washington University for faculty service of more than twenty-five years; on the medical board and the board of governors of the Columbia Hospital for Women and Lying-In Asylum; consultant in gynecology at Children's Hospital; on the staffs of George Washington University and Garfield hospitals; died December 11, aged 59.

Charles Edward Conrad * Harrisonburg, Va.; University of Virginia Department of Medicine, Charlottesville, 1905; specialist certified by the American Board of Pediatrics; served as president of the Rockingham County Medical Society, the Medical Association of the Valley of Virginia and the Virginia Pediatric Society; charter member of the American Academy of Pediatrics; formerly chairman of the pediatric section of the Southern Medical Association; past president of the Harrisonburg Rotary Club; received the Silver Beaver award for meritorious leadership in the Boy Scouts of America; life member of the Rockingham Library Association; on the staff of the Rockingham Memorial Hospital; died in the University of Virginia Hospital, Charlottesville, November 1, aged 65.

Norman Edward Ditman * Palm Beach, Fla.; Columbia University College of Physicians and Surgeons, New York, 1900; formerly instructor in pathology at his alma mater; served on the staffs of St. Luke's, Roosevelt and Sloane Maternity hospitals in New York; on the staffs of the

Good Samaritan and St. Mary's hospitals, West Palm Beach; veteran of the Spanish-American War; member of the National Defense Council and served as medical director of a Red Cross hospital during World War I; served for two years as head of the public health division of the New York Academy of Medicine and for many years as a director of the department of industrial hygiene of the American Museum of Safety; formerly visiting physician at Ritz-Carlton, Pierre and Gladstone hotels, New York; died December 15, aged 67, of coronary thrombosis.

John Kerr Pepper * Winston-Salem, N. C.; College of Physicians and Surgeons, Baltimore, 1907; fellow of the American College of Physicians; served as president of the Radiological Society of North Carolina; past president of the Forsyth County Medical Society; formerly a member of the state medical board for nurses; charter member of the Kiwanis Club and served as lieutenant governor of the third district of the Kiwanis International; member of the county board of health; on the staffs of the City Memorial and North Carolina Baptist hospitals; died October 31, aged 67, of heart disease and pneumonia.

Samuel Taylor Bassett, University City, Mo.; Barnes Medical College, St. Louis, 1905; Washington University School of Medicine, St. Louis, 1907; member of the American Medical Association; on the staff of the Missouri Baptist Hospital, St.

GEORGE E. FOLLANSBEE, M.D., 1871-1945

Louis, where he died November 1, aged 71, of pituitary dysfunction and lobar pneumonia.

Eugene Langdon Beard, Garber, Okla.; Ensworth Medical College, St. Joseph, Mo., 1908; city physician; died August 22, aged 58.

Nathan George Bennett, Haviland, Kan.; Barnes Medical College, St. Louis, 1902; member of the American Medical Association; died October 8, aged 71, of coronary thrombosis.

Robert Wilson Clark, Venango, Pa.; Western Reserve University Medical Department, Cleveland, 1884; member of the American Medical Association; died in the Meadville City Hospital, Meadville, August 28, aged 84, of senility.

Jake A. Hook, Pleasant Plains, Ark.; Memphis (Tenn.) Hospital Medical College, 1904; died October 14, aged 61, of lymphatic leukemia.

George T. King, Elgin, Texas; University of Louisville (Ky.) Medical Department, 1886; died October 14, aged 82, of cerebral hemorrhage and generalized arteriosclerosis.

William Thomas McBrayer, Atlanta, Ga.; Emory University School of Medicine, Atlanta, 1942; served an internship and residency in surgery at the Grady Memorial Hospital, where he died October 23, aged 25, of bronchiogenic carcinoma.

Royall J. Miller, Atlanta, Ga.; University of Georgia Medical Department, Augusta, 1881; died in the Georgia Baptist Hospital October 17, aged 83, of myocardial failure and uremia.

Weston Peter Miller, Eunice, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1909; member of the American Medical Association; died in the Touro Infirmary, New Orleans, October 28, aged 58.

John White Moore, Gloversville, N. Y.; Vanderbilt University School of Medicine, Nashville, 1904; formerly a medical inspector of the schools in Nashville, Tenn.; served on the staff of the Nathan Littauer Hospital; died October 6, aged 66.

Andrew Kincannon Naugle, West Point, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1905; served on the pension board of the Spanish-American Veterans; at one time Clay County health officer; a director of the Bank of West Point; served on the city school board for many years; died October 29, aged 66, of cerebral hemorrhage.

Alice Antoinette Pendleton, Cleveland; University of Oklahoma School of Medicine, Oklahoma City, 1937; served an internship at the Bethany Methodist Hospital, Kansas City, Kan.; died in the City Hospital October 14, aged 42.

Alva Sherman Pinto © Omaha; John A. Creighton Medical College, Omaha, 1898; health officer of Omaha; served on a Philippine cholera commission from 1900 to 1903; veteran of the Spanish-American War and World War I; on the staff of the Doctors' and St. Joseph's hospitals; died December 7, aged 72, of coronary occlusion.

Clara Stone, Los Angeles; Chicago College of Medicine and Surgery, 1912; died September 7, aged 60, of hypertensive heart disease.

Elmer John Tiedemann, Adrian, Minn.; Rush Medical College, Chicago, 1886; died October 28, aged 83, of acute myocardial failure.

John Kirtland Tressel, Alliance, Ohio; University of Wooster Medical Department, Cleveland, 1902; served during the Spanish-American War and World War I; died in the Veterans Administration Facility, Dayton, October 13, aged 66, of hypertensive heart disease.

John Pierce Turk, Nelson, Ga.; Atlanta College of Physicians and Surgeons, 1904; member of the American Medical Association; formerly mayor of Nelson; member of the board of education and Pickens County Selective Service Board; died October 26, aged 65, of coronary thrombosis.

Ralph Wallace Warnock © St. Paul; University of Minnesota Medical School, Minneapolis, 1921; specialist certified by the American Board of Internal Medicine; clinical instructor, division of internal medicine, at his alma mater; served an internship at the Minneapolis General Hospital; on the staffs of the Ancker, St. John's, Charles T. Miller and St. Luke's hospitals; died October 1, aged 53.

Hartwell Weaver, Dickson, Tenn.; Vanderbilt University School of Medicine, Nashville, 1910; member of the American Medical Association; died September 17, aged 58.

Eugene Griffith Wilcox, Drummond, Mont.; Northwestern University Medical School, Chicago, 1924; first lieutenant, medical reserve corps, U. S. Army, not on active duty; died in Missoula October 11, aged 50, of carcinoma of the hand.

DIED IN MILITARY SERVICE

Alfred Lee Clifton © Medical Director, Captain, U. S. Navy, Smyrna, Del.; University of Pennsylvania Department of Medicine, Philadelphia, 1906; commissioned a lieutenant (jg) in the medical corps of the U. S. Navy on July 15, 1908; later promoted to lieutenant, lieutenant commander, commander and captain; fellow of the American College of Surgeons; medical officer in command of the United States Naval Convalescent Hospital, Sun Valley, Ketchum, Idaho, where he died February 22, aged 62, of arteriosclerotic coronary heart disease.

Wilbur Leroy Edgerton © Baton Rouge, La.; Louisiana State University School of Medicine, New Orleans, 1939; served an internship at the Charity Hospital in New Orleans; commissioned a first lieutenant in the medical corps, Army of the United States, on July 30, 1942; later promoted to captain; a flight surgeon; died in the Asiatic area September 17, aged 30, of pneumonia.

Rudolph M. Hecht © Chicago; University of Illinois College of Medicine, Chicago, 1933; member of the American Academy of Dermatology and Syphilology and the American Association for the Study of Allergy; served an internship at the Michael Reese Hospital; commissioned a captain in the medical corps, Army of the United States, on Sept. 28, 1942; died in the European theater of operations September 16, aged 38, of injuries incurred in a vehicle accident.

Paul Hubbard Lowry, Syracuse, N. Y.; Syracuse University College of Medicine, 1922; member of the American Medical Association; fellow of the American College of Surgeons; instructor in clinical surgery at his alma mater; on the staff of the Hospital of the Good Shepherd, Syracuse University; surgeon, Syracuse University Infirmary; for many years physician of the Syracuse University athletic teams; commissioned a major in the medical corps of the Army of the United States on Aug. 12, 1941; began active duty on Sept. 1, 1942; died in Camp Joseph T. Robinson, Ark., November 5, aged 47.

Edward Patrick Manning, Milton, Mass.; Tufts College Medical School, Boston, 1937; served an internship at the Boston City Hospital; commissioned a lieutenant (jg) in the medical corps, U. S. Naval Reserve, on Feb. 7, 1941; later promoted to lieutenant and lieutenant commander; died in the U. S. Naval Hospital, Portsmouth, Va., August 21, aged 34, of subacute bacterial endocarditis.

Charles Walton Purcell, Danville, Va.; University of Virginia Department of Medicine, Charlottesville, 1933; member of the American Medical Association; served an internship at the Orange Memorial Hospital, Orange, N. J., and the New York Post-Graduate Medical School and Hospital, New York; served a residency in pediatrics at the University of Virginia Hospital, University, Va.; commissioned a first lieutenant in the medical corps, Army of the United States, on Aug. 20, 1942; later promoted to captain; died near Napa, Calif., November 11, aged 36, of injuries received in an automobile accident.

William Emmett Ryan © Midland, Texas; Baylor University College of Medicine, Dallas, 1925; fellow of the American College of Surgeons; past president of the Ector-Midland-Martin-Howard-Andrews-Glasscock Counties Medical Society; served as counselor and past president of the Second District of the State Medical Association of Texas; for many years served as city and county health officer; owned and operated the Ryan Hospital and Clinic from 1931 to 1942; charter member and past president of the Rotary Club; for many years director of the chamber of commerce, serving as president of that organization; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on June 1, 1925; promoted to captain; began active duty as a major, medical corps, Army of the United States, Sept. 25, 1942; later promoted to lieutenant colonel; died near Vendome, France, September 19, aged 45, of injuries incurred in a vehicle accident.

Joseph Duerson Stout © Washington, D. C.; George Washington University School of Medicine, Washington, 1913; Army Medical School, 1918; served during World War I; formerly professor of neurology at his alma mater; commissioned a major in the medical reserve corps, U. S. Army, March 14, 1925; began active duty as a lieutenant colonel in the Army of the United States March 5, 1941; died in England, November 6, aged 57, of cerebral hemorrhage.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Hyperthyroidism and Pregnancy. I. Kibel.—p. 553.

Rh Factor in Relation to Hemolytic Anemia of New-born Infant.—Lubinski and his collaborators consider it desirable to abandon the previous terminology, such as erythroblastosis fetalis, icterus gravis, congenital anemia and hydrops fetalis, which designate some of the clinical manifestations associated with the disease. Since hemolytic anemia is the most important feature, the term hemolytic anemia of the newborn seems appropriate for all forms of the disease. The authors studied 6 cases of hemolytic anemia of the newborn which occurred in six families. There was evidence that 7 other infants in these families had probably suffered from this disease. Common to all cases tested was the combination of the following conditions: The mother was Rh negative, the father was Rh positive (only one father was not available for testing), and the infant was Rh positive. All the mothers had anti Rh agglutinins in their serums. Immunization of an Rh negative woman by repeated transfusions of presumably Rh positive blood was later followed by fatal hemolytic anemia of her first newborn infant. Rh negative women should not be transfused with Rh positive blood, to prevent the possibility of this undesirable effect on future Rh positive offspring. A possible role of complement and of the liberation of hemolysins after the destruction of red blood cells in the clinical picture of hemolytic anemia of the newborn is discussed. No correlation was found between the titer of anti Rh agglutinins in the mother's serum at parturition and the severity of the disease in her newborn infant. As the treatment of choice for this disease, the infant should receive a transfusion of a concentrated suspension of washed Rh negative red blood cells as early as possible, and this should be repeated as often as may be necessary. A suspension of washed cells from the mother's blood may be used if no suitable donor is available. Washed cells from the mother's blood should be used in any case in which the mother and her newborn infant who shows evidence of the disease are both Rh positive or both Rh negative.

Struma Ovarii.—Gusberg and Danforth state that there have been 8 cases of struma ovarii recorded in the pathologic files of the Sloane Hospital for Women in the past twenty years. This represents 2.7 per cent of 297 ovarian teratomas of all types which were examined during the same period. Of the 8 cases, 7 presented the usual clinical symptoms which accompany benign ovarian tumors: intermittent abdominal pain,

painless pelvic or abdominal masses and in 1 instance acute abdominal pain due to torsion of the pedicle. In these cases the presence of thyroid tissue is only of pathologic interest. The cystic tumors were generally multilocular, and 3 of the 7 contained epidermoid elements characteristic of the ordinary dermoid cyst. Microscopically, none of these cases showed evidence of hyperplastic changes in the thyroid tissue. The eighth case presented a symptom complex of an unusual nature. A huge struma colli, a large struma ovarii and evident thyrotoxicosis were coexistent. The actual role of the ovarian tumor in the production of hyperthyroidism is problematic. The microscopic findings, the probable mechanical contribution of a huge goiter to the elevated basal metabolic rate and the persistent tachycardia after the thyroidectomy might be considered as presumptive evidence that the ovarian tumor contributed to the thyrotoxicosis. That struma ovarii is capable of producing, or at least contributing to, thyrotoxicosis is established. It is this ability which distinguishes the ovarian struma among all ovarian neoplasms. Cases of functioning ovarian struma may easily escape diagnosis, either through failure to appreciate mild hyperthyroid symptoms or through chance avoidance of thyroid tissue in the sectioning of large ovarian teratomas.

Vagitus Uterinus with Prolapse of Umbilical Cord.—Kitzmiller and Mitchell cited three conditions which must be present in order for crying in utero to become evident: 1. The membranes must have ruptured. 2. There is usually some operative manipulation to stimulate the infant. 3. There must be entrance of air into the uterus. Mitchell describes the delivery of a woman aged 29 in whom the membranes became visible twenty-five minutes after admission. A membrane-covered mass protruded from the vagina. The membranes ruptured spontaneously, and a loop of umbilical cord about 30 cm. in length was found prolapsed. Shortly thereafter the infant was heard crying loudly enough to be audible to all in the room. Fetal heart tones were 100 per minute but were still strong. An unsuccessful attempt was made to replace the loop of cord, and it was decided to deliver by version and breech extraction. Without unusual difficulty a female stillborn infant which weighed 6 pounds 2 ounces (2,900 Gm.) was delivered by combined podalic version and breech extraction.

Fate of Young Children with Tuberculosis.—Mitchell and Willis say that from 1922 until 1938, when the present study was ended, 2,091 patients up to age 14 were admitted to the Children's Division of the Maybury Sanatorium. Of these, 243 were 3 years of age or younger and were studied by Mitchell and Willis. Some of the patients of this group were brought to the hospital because of manifest illness, but the larger number were given diagnoses in the course of contact examinations and most of them were without symptoms. All of the 243 had tuberculosis. No one was admitted on the basis of a tuberculin reaction alone. Their diseases were classified on the basis of the x-ray appearance into primary and reinfection types. The outlook was distinctly worse for the reinfection than for the primary type of tuberculosis. With both the primary and reinfection types of tuberculosis the Negro child had a poorer chance

of survival than the white child. The younger children (birth through 18 months) had a much higher fatality than the older ones (19 to 36 months). The children discharged alive who had remained in the hospital longer than three months had a decidedly more favorable fatality experience than those who had remained a shorter period. (Fifty-eight per cent of all the children remained in the hospital longer than one year.) The children discharged with the disease apparently arrested had a more favorable subsequent fatality experience than those discharged with a less favorable clinical status. Nearly all of the children admitted with active primary lesions who were hospitalized until they could be discharged with apparently arrested tuberculosis were found, over a rather long period of follow-up, to have remained well. For this reason, a plea is made that children with active tuberculosis, with or without symptoms, be provided with adequate treatment in a hospital.

Institutional Cooking Methods and Thiamine Content of Potatoes.—Wertz and Weir analyzed foods obtained at a college dining hall which served three meals a day to 500 students. The potatoes for the noon and the evening meal were peeled with an electric abrasive peeler between 9 and 10 o'clock in the forenoon. The potatoes which were served for

the noon meal were washed and cooked immediately, whereas those used for the evening meal were placed in a vat and soaked for approximately six hours in tap water, which was slowly running into and out of the vat. On removal from the water the potatoes were placed in perforated metal trays in a steam oven and subjected to steam at a temperature of approximately 225 F. for one hour. If the potatoes were to be mashed, this was done immediately by whipping in an electric mixer with fat, salt, pepper and milk. The mashing process took about five minutes. During the interval between the completion of the cooking and the serving, the potatoes, either whole or mashed, were placed in trays in a steam warming oven at a temperature of 157 F. The time of holding ranged from fifty to one hundred and twenty minutes. The loss in thiamine incurred at each step has been computed on a dry weight basis. Small losses resulted from soaking the potato prior to cooking and from holding the potato in a steam oven for a period as long as one and a half hours. The greatest loss, 14.1 per cent of the original value for thiamine, occurred during the steam cooking process. The mashing of the potato did not appear to be destructive of the thiamine. The overall loss in thiamine exclusive of that during soaking approximated 20 per cent.

Effects of Variations in Dietary Protein on Men Doing Manual Work.—Darling and his associates made studies on 22 volunteers from a civilian public service camp, who continued on the work regimen of the camp. At the start each subject was given a thorough physical examination, clinical laboratory examination of blood and urine and blood chemical estimation. Assessment of physical fitness each week was by means of the so-called pack test, in which the subject, wearing a rucksack weighted to approximately $\frac{1}{2}$ his body weight, stepped up onto a 16 inch platform and back down onto the floor once each two seconds. The stepping exercise was terminated at five minutes; after stopping, the pulse was counted for three periods: one to one and one-half minutes, two to two and one-half minutes and four to four and one-half minutes of the recovery period. From these data a numerical score was calculated. The experiment was continued for eight weeks on the modified diet. Within two months no measurable influence either deleterious or beneficial could be observed on the physical vigor or efficiency of 8 healthy young men subsisting on a diet adequate in calories but restricted in protein. The daily protein intake averaged 50 to 55 Gm, little of which was of animal origin. Similarly no beneficial or harmful effect could be observed in two months on 8 men subsisting on a diet providing 160 Gm. or more of protein, mostly first class. These studies fail to confirm Clutenden's conclusions that a restricted protein diet improves physical well being. His conclusion that there is no impairment of health by such a diet is completely supported.

Plateau Test in Breast Carcinoma.—Jackson and Severance describe a "plateau" test, which is produced by the following manipulation: The flat of a hand is placed on each side of the tumor. Gently the hands are brought toward each other with sufficient pressure to produce a rounded surface between them and over the tumor. This surface is likened to the top of a hill. In a normal breast, or in the presence of a benign tumor, there remains a perfectly rounded top. In the presence of an early malignant growth there is a flattening of this top—a flattening containing fine irregularities; hence the name plateau. After working with this test for several years the authors have found that the zone just above the nipple does not lend itself to an accurate interpretation, and consequently they no longer use the test in this area. Chronic cystic mastitis contributed the greatest error in false positives, since this lesion gives a smooth flat plateau at times, whereas in cancer the plateau is irregular and often has fine lines and indentations on its surface.

Nicotinic Acid in Treatment of Angina Pectoris.—Stokes studied the effect of nicotinic acid, nicotinamide, ascorbic acid, a gentian mixture and glyceryl trinitrate on 10 patients with effort angina. Eight of the 10 patients had had cardiac infarction at some previous date, but sufficient time had elapsed for maximum myocardial recovery to occur; 1 of the remaining 2 had hypertension, and the other with classic anginal attacks had a normal cardiogram. All were studied as ambulant outpatients. Clinical examination included cardioscopy and cardiography. Each test period lasted at least one week, and this was often repeated. There was no particular sequence, and a placebo in the form of ascorbic acid or a gentian mixture was interspersed at intervals. Nicotinic acid was employed in doses of 50 to 100 mg. prophylactically and for the direct relief of the painful attack in some of the cases. In all cases during further trial periods it was given in regular doses of 25 or 50 mg. up to 200 mg. daily. Similarly nicotinamide was given in amounts up to 400 mg. in a day. No greater benefit resulted from nicotinic acid or from nicotinamide than from a placebo. Changes in the electrocardiogram of cardiac ischemia in man following the administration of nicotinic acid suggest that the drug can improve coronary blood flow; but this results only from a dosage large enough to produce peripheral flushing, which in itself is an uncertain and unpleasant effect. Once again glyceryl trinitrate has shown that it has no equal in the treatment of angina pectoris, and nicotinic acid has no claim to routine use in this complaint.

Revista Médica Brasileira, Rio de Janeiro

17:35-113 (July) 1944. Partial Index

- *Tuberculous Bronchopathies. R. A. Piaggio Blanco and J. C. Dighiero.—p. 35.

Causal Factors of Curves of Tuberculinization. P. Purriel.—p. 45.

The Tuberculous Bronchopathies.—Piaggio Blanco and Dighiero classify tracheobronchial tuberculosis as the primary forms and those complicated by lymph node or pulmonary tuberculosis. The signs of primary tracheobronchial tuberculosis are those produced by local irritation followed by chronic fibrosis and chronic bronchial obstruction. The asthmatic and chronic bronchitic forms are most frequent. Tracheobronchial tuberculosis is frequent in primary pulmonary tuberculosis of children and adolescents and in secondary and tertiary pulmonary tuberculosis in adults. The diagnosis is established by bronchoscopy. The bronchoscopic aspects vary with the seat of the lesion and the evolutionary stage of the latter. The bronchial mucosa is frequently the seat of both tuberculous and nontuberculous lesions. The bronchi are either compressed by the enlarged lymph nodes or retracted by sclerosis of the pulmonary lesions. The evolution of tuberculous bronchial lesions runs parallel with the evolution of the tuberculous process in the involved lobe. Acute exudative bronchial tuberculosis appears in some cases two to six years after the regression of the pulmonary tuberculosis and its calcification. Bronchoscopy is the procedure of choice in the diagnosis of the lesion. It is harmless if contraindications are respected. The contraindications are laryngeal ulcers, spitting of blood and acute bilateral tuberculosis. The author performed 1,200 bronchoscopies without serious reactions. Biopsy of the bronchial mucosa is not to be performed.

Book Notices

The Diseases of the Endocrine Glands. By Hermann Zondek, M.D., Director of the Medical Division, Bikur Cholim Hospital, Jerusalem. Translated by Carl Prausnitz Gies, M.D., M.R.C.S., L.R.C.P. Fourth (Second English) edition. Cloth. Price, \$11. Pp. 496, with 180 illustrations. Baltimore: William Wood & Company, 1944.

This edition of the widely known textbook on endocrinology has been brought down to date by inclusion of recent investigative material. Approximately the first quarter of the book is devoted to a general discussion of endocrinology in which the author attempts to correlate as much as possible of what has been published in the field of experimental and clinical endocrinology and of much that is known about relationships of this field with nutrition, neurology and certain other parts of physiology and pathology. The larger section of the volume is devoted to a series of chapters on a conventional clinical grouping of endocrine disorders, frequently illustrated with specific cases. The author introduces some chapters about less conventional topics, such as diencephalic disease, hyperostosis frontalis, the Schueller-Hand-Christian syndrome, osteomalacia, which is now being considered a nutritional disorder, and the status thymicolymphaticus. It is curious that there is no section on diabetes mellitus except a very short chapter on diabetes of a pituitary type. Nevertheless more space is given to a chapter on hyperinsulinism.

One of the characteristics of this author's work is his continuing tendency to rationalize all possible situations as he describes them. This is most frequently done by invoking the relationships between hormones and the nervous system or by comments on differences in the results of hormone stimulation depending on the nature of the end organ and its condition at the time.

The bibliography is arranged by chapters and by the names of the authors and occupies forty-six pages. This suggests that the volume affords an extensive guide to the now large literature of experimental and clinical endocrinology. It is perhaps not surprising in view of the author's chief experience in Germany that a large proportion of the bibliography is devoted to the German journal literature and that the references to work in the last decade in North America are relatively fewer than is the case in most American publications in this field. The book is very readable and will be welcomed by those who want an extensive presentation of the point of view of one of Europe's older clinical endocrinologists.

Textbook of Histology for Medical Students. By Evelyn E. Hewel, D.Sc. Third edition. Cloth. Price, 17s. 6d. Pp. 364, with 344 illustrations. London: William Heinemann, Ltd.; St. Louis: C. V. Mosby Company, 1944.

This textbook of histology is announced as being prepared especially for medical students. In this it does not differ from most of the other textbooks on the subject. As stated in the preface, the author has tried to emphasize this purpose by omission of "detail that is of academic interest rather than of practical importance." Apart from the question of whether the teaching of medical students on such a basis is desirable, there remains the problem of determining just what is "detail of academic interest" and what is of "practical importance." There is no evidence in the text that the author has been able to make a sharp distinction between these. The abbreviation of the text is mainly due to omission of discussion and description such as the reviewer feels is necessary to give the student a clear insight into our present knowledge and lack of knowledge of the structure and function of the various cells, tissues and organs. The author states in the preface that references are given for further information. However, the references are few and do not concern original papers or reviews that might stimulate the student but general textbooks.

The text contains a few confusing statements. On page 11 the cells of transitional epithelium are described as "protoplasmic and soft." On page 88 it is said that a nerve cell has "no true cell wall (!) but merely a covering membrane," while in the same chapter on page 92 we find "a nerve cell has no true cell membrane, the external surface being naked."

The illustrations consist of photomicrographs and diagrammatic drawings. The first are good but inadequately labeled;

the majority of the latter are unacceptable. The book contains a series of photographs of brain stem sections. For a description of them the student is referred to textbooks of anatomy or neurology.

An interesting feature of this book is that each chapter is followed by a description of the reaction of tissues to various physiologic and pathologic conditions. However, the possible goal of this, to aid the student in the transition to pathology, is not reached because of the epigrammatic character of the descriptions.

Latrodectus mactans y latrodectismo: Estudio experimental y clínico. Por Rafael R. L. Sampayo. Tesis de doctorado en medicina, Universidad nacional de Buenos Aires, Facultad de ciencias médicas, Instituto de fisiología. Paper. Pp. 227, with 48 illustrations. Buenos Aires, 1942.

In all probability this is the most comprehensive monograph ever published on spiders of the black widow group. The study was suggested to the author by Dr. B. A. Houssay, in whose laboratory most of its experimental part was carried out. The study is systematic. It starts with the history of latrodectism, zoologic place of *Latrodectus* and its biology (ecologic data, longevity, habitat, reproduction and so on), which is followed by a chapter by Dr. J. Porto on the structure of the poisonous glands of the insects. Then there is an analysis of what is known on the chemical components of the venom, effects on other animals and pharmacology of the active principles. From the experiments of the author, sometimes duplicating results already known, it results that the poison exerts its effects on the central nervous system with subsequent rise of the blood pressure and changes in the T wave of the electrocardiogram and respiratory disturbances. The effects on the blood, bronchi, intestine and uterus are also carefully studied. Some of these effects are neutralized by specific antisera. Other chapters deal with the treatment of intoxication in human beings, manufacturing and purification of specific antisera, clinical study of latrodectism and social importance of the condition. The references given are 923, among which there is an imposing amount of those from Latin American workers. The illustrations are excellent.

Diseases of the Digestive System. Edited by Sidney A. Portis, B.S., M.D., F.A.C.P., Associate Professor of Medicine, University of Illinois Medical School, Chicago. Second edition. Cloth. Price, \$11. Pp. 932, with 182 illustrations. Philadelphia: Lea & Febiger, 1944.

This newly revised and rearranged compendium is written by forty-eight different authors in the field of digestive diseases. The entire gastrointestinal tract, the liver, the gallbladder and the pancreas are discussed. There are separate chapters by recognized authors on the anatomy and physiology of the major organs. Chapters are devoted to gastrointestinal manifestations of cardiovascular, renal, urologic, neurogenic, psychosomatic, endocrinologic and allergic diseases. Excellent chapters on intestinal protozoal and metazoal infestations are included. In this new edition the psychosomatic aspects of digestive disease have been especially stressed. The writing of each chapter has been left to its particular author. This gives variety and freshness of approach but leads also to inequalities of treatment, varying from the extraordinarily concise chapter on linitis plastica, by Aaron, to the more diffuse chapter, by Gaither, on gallbladder disease. The majority of chapters are quite complete but concise. The result is a small book, easily carried, printed in large type on good paper and well illustrated. It can be recommended to students and practitioners alike as a practical book of easy reference, well up to date in regard to new discoveries, diagnosis and treatment.

Special Delivery: The Expectant Mother's Handbook. By B. D. Rosenberg, M.D. Cloth. Price, \$2. Pp. 96, with 43 illustrations by Gladys McHugh. Chicago & New York: Ziff-Davis Publishing Company, 1944.

Under the catchy title this small book is an attempt on the part of a physician to present the story of childbirth to a lay audience in such a way as to remove the fears and fancies surrounding this physiologic function. He accomplishes his purpose by means of numerous beautifully executed illustrations by a well known medical artist and descriptive material to elucidate the pictures. Although the book may hold some interest for potential mothers, it doesn't replace the antepartum information provided by many well known textbooks.

Queries and Minor Notes

MUSCULAR CRAMPS IN NORMAL PERSONS

To the Editor.—Please tell me the cause of muscle cramps in athletes aside from so-called heat cramps. Does the calcium balance have any part in this condition? Is there any preventive?

M.D., Illinois.

ANSWER.—There is surprisingly little known about the cramps which develop in normal persons during exercise, at night when turning or stretching, after yawning or when some unusual position is held excessively long. In these circumstances an intense involuntary contraction is superimposed on the voluntary activity in much the same manner as occurs in the pathologic state described as myokymia. Apparently the contraction is accompanied by spike action potentials and therefore is more closely related to normal voluntary contractions than to the so-called contractures in which spike potentials are not seen. The cause of the cramp lies in an abnormal sensitivity of the muscle fiber at or near the motor end-plate which permits the appearance of series of autogenic discharges which force the muscle into an intense tetanic contraction. This process is evidently intensified by fatigue, insufficient blood supply, mild myositis or neuritis, vitamin B deficiency, alkalosis, low serum calcium and a variety of congenital diseases of the muscles, and the cramps seen in these conditions have clear affinities with those observed in normal persons. Collip and Backus have suggested that cramps in swimmers and runners might be due to tissue alkalosis due to hyperventilation and loss of carbon dioxide in excess of production. If this should be the case, calcium administration might on theoretical grounds be useful, although the difficulty of maintaining an increased serum calcium in such circumstances would be great. In addition Denny-Brown and Pennypacker have reported that calcium was ineffective in controlling cramps occurring in patients with myokymia.

The observation that drugs, such as neostigmine, which potentiate acetylcholine activity increase the incidence of myogenic muscle contractions related to cramps induced Moss and Herrmann to employ quinine, which has a curare-like action, antagonistic to acetylcholine, to prevent night cramps, and they report a number of cases successfully treated in this manner. This drug might therefore prove useful in reducing the incidence of cramps in athletes, without harm to voluntary muscular performance.

NASAL SIPHONS

To the Editor.—I would appreciate information concerning the Nichols nasal siphon. Is this an acceptable apparatus for cleansing and irrigating sinuses? Will it evacuate the sinuses of pus and thick discharges? Is it sound practice to use it for acute and chronic sinusitis?

A. L. Henrichsen, M.D., Van Nuys, Calif.

ANSWER.—Siphons of this type are in use and are prescribed by physicians under proper precautions. They are suitable for selected conditions and patients. The siphon will certainly cleanse the nasal passages, and the one mentioned, because of its suction aspects, may conceivably remove secretion from the sinuses.

There is a risk, however, in the use of any siphon: if the procedure is improperly carried out, infected nasal secretions and irrigating fluid may be forced up into the eustachian tubes with a resultant acute otitis media.

Patients using nasal irrigations must be warned of its dangers and instructed as to its proper use. They should be of an age and intelligence sufficient to assure their following instructions carefully.

It might be best to reserve the use of siphonage for chronic and subacute instances of sinusitis and avoid its use in the more acute types.

EXPOSURE OF MAPHARSEN SOLUTIONS TO AIR

To the Editor.—In some clinics for the treatment of syphilis the method of preparing the mapharsen is as follows: An ampule of 0.40 Gm. or 0.60 Gm. (ten dose) size of mapharsen is dissolved in 100 cc. of distilled water with careful sterile technic. The solution, with dissolved mapharsen, remains in the rubber stoppered bottle. The dose required for each patient is removed from the bottle as needed. This subject is of clinical importance, and in clinics with a large case load it is time saving to prepare the mapharsen solution before the clinic begins, if the efficiency of the treatment is not reduced by such a method. Has any clinical or experimental information been collected to determine that the therapeutic efficiency of mapharsen solution is lessened when prepared two to four hours previously? The statement appears in Moore's Modern Treatment of Syphilis (ed. 2, Springfield, Ill.; Charles C Thomas, 1943, p. 68) that mapharsen "oxidizes slowly and upon oxidation becomes less toxic as well as less efficient therapeutically." However, in the Parke-Davis instruction folder the statement appears "Mapharsen solution may be allowed to stand for several hours exposed to air with no increase in toxicity or loss in efficacy." References to the literature and any other information on this subject will be appreciated.

Laurence J. Underwood, M.D., Huntington Park, Calif.

ANSWER.—The only reference in the literature on the point raised by the enquirer is in the article by Tatum and Cooper "Experimental Study of Mapharsen as an Antisyphilitic Agent (*J. Pharmacol. & Exper. Therap.* 50:198 [Feb.] 1934). Here it is clearly stated that when mapharsen solution is allowed to stand exposed to the air for several days both toxicity and therapeutic efficiency are somewhat decreased. There is no information that there is a significant decrease in therapeutic efficiency when such a solution is allowed to stand for only a few hours. The clinic procedure referred to in the query is customary in many clinics for the treatment of syphilis.

It is understood that Dr. A. L. Tatum of the University of Wisconsin has done further experimental work on the subject and has accumulated a good deal of unpublished evidence on the effect of aeration on mapharsen solutions.

OSTEOPATHIC REPORT

To the Editor.—Recently a patient presented me with a report which he had received from an osteopathic hospital. The report read as follows: "In the standing position, the articular surface of the left femur, the left iliac crest and the contact of the perpendicular to the long axis of the sacrum with the left femoral plane were respectively 0.6, 0.7 and 1.8 cm. nearer the floor than the corresponding points on the right. The mid-point of the 1st sacral segment and the symphysis were respectively 0.4 and 0.6 cm. to the right of the midheel line. Lateroflexion change to the left of the 4th and 5th lumbar segments was observed with compensatory lateroflexion change to the right of the upper lumbar segments." The patient wanted to know what was wrong. Can you give me help in making a diagnosis from this report?

Albert Torney, M.D., Madison, Wis.

ANSWER.—This report from an osteopathic hospital is quite meaningless to an orthopedist. It is utterly impossible to base an opinion on any recognizable diagnosis on this report.

IRRITATION OF EYES FROM PENTACHLOROPHENOL

To the Editor.—I have been asked by one of the local industries whether nitrocellulose and pentachlorophenol are injurious to the eyes, or the thinner also used: ethyl acetate and butyl alcohol. Would the fumes of these be irritating?

W. Edward McGarvey, M.D., Jackson, Mich.

ANSWER.—With the exception of nitrocellulose, all of the substances mentioned may be irritating to the eyes if applied directly. Nitrocellulose is a solid, probably has no melting point and does not give off vapors. If ignited, nitrocellulose decomposes with the formation of the dangerous oxides of nitrogen, fully capable of eye injury but more likely to involve the respiratory tract. Pentachlorophenol is a dangerous chemical, but because of its high boiling point (310 C.) it is little likely to emit harmful vapors when cold. When heated, this substance gives rise to highly pungent odors and irritation. Likewise its dust is irritating. Ethyl acetate and butyl alcohol fall into less harmful categories. At about the level of 150 parts per million of air, ethyl acetate may bring about ocular inflammation, although only a slightly lower level is regarded as safe for extended exposures. Butyl alcohol usually is rated as being about three times as toxic as ethyl alcohol, but it is recognized that minor eye irritation from its vapors exceeds this proportion. Pentachlorophenol is the substance in this group most likely to cause irritation of the eyes.

PREGNANCY IN RAYNAUD'S DISEASE

To the Editor.—A patient who has Raynaud's disease is contemplating pregnancy. Is pregnancy advisable under such circumstances?

Ben N. Miller, M.D., Columbia, S. C.

ANSWER.—Pregnancy does not have an adverse effect on Raynaud's disease.

THE EFFECTS OF BIOCHEMICAL THERAPEUSIS IN CARCINOMA OF THE PROSTATE

FURTHER OBSERVATIONS

WILLIAM P. HERBST, M.D.
WASHINGTON, D. C.

In June 1940 Drs. Huggins and Clark presented an exhibit at the meeting of the American Medical Association in New York which demonstrated the fact that the administration of diethylstilbestrol to dogs with benign hyperplasia of the prostate resulted in atrophy of the epithelial cells and a decrease in the total bulk of the prostate gland. In the following August a patient with an extensive inoperable malignant prostate gland presented himself for treatment. His general condition was such that no surgical or instrumental procedure was justifiable. With the idea in mind that, if diethylstilbestrol produced some change in the biochemical soil in the dog which resulted in atrophy of the prostatic epithelial cells, estradiol dipropionate or similar biologic substances might modify the soil of a human being with prostatic carcinoma in such a way that carcinoma cells might atrophy, this patient was given 1 mg. of estradiol dipropionate by injection into the deltoid. The immediate change observed in this person was most spectacular. Instead of having to void with severe pain in a dribble at hourly intervals, he had to void only at periods of from every four to six hours, and instead of a dribble the urine came in a definite stream. This occurred in twenty-four hours. Following this experience a number of patients with benign and malignant prostatic obstructions were treated, and the results were reported before the Mid-Atlantic Section of the American Urological Association in March 1941 at Washington, D. C. Since that time the contribution of Huggins and others on certain chemical aspects of the control of prostatic carcinoma by castration have stimulated a hopeful interest in the chemical control of cancer.

It seems that at the present time the human race is going through an evolutionary period of an increasing incidence of cancer partly because of a myriad of already known carcinogenic substances with which we come in contact in our daily environment. The abstracted case reports which follow are presented to demonstrate the extreme variation in the clinical course in this form of treatment and to provide material for discussion:

REPORT OF CASES

CASE 1.—A man aged 69 in poor condition had a large inoperable mass in the rectum, extreme dysuria and a frequency of hourly voiding. One mg. of estradiol dipropionate by hypo-

dermic injection changed voiding to nocturia only four times and he voided with comfort in a stream instead of a dribble. From Aug. 14, 1940 to the present time this patient has been under control most of the time and is now definitely under control. The dose of estradiol dipropionate varied from a series of nine injections at the rate of three a week with varying periods of administration to the present dose of 0.5 mg. of ethinyl estradiol orally per day and 5 mg. of diethylstilbestrol every two weeks by hypodermic in the office. In addition to these chemicals he is getting two vitamin B complex capsules, 10 mg. of thiamine hydrochloride and three calcium gluconate tablets 15 grains (1 Gm.) orally daily. Calcium gluconate 15 grains is given intravenously in the office every two weeks when the patient gets the 5 mg. of diethylstilbestrol by hypodermic injection. At one time he developed a purpuric-like skin picture phenomenon with no abnormal blood findings, but this has been controlled to date by calcium. A resection was done on June 2, 1942, because of dysuria and obstruction. He had successive thrombophlebitic attacks involving three extremities and the lungs, in order, which resulted in a critical illness of three months' duration and which was controlled by calcium therapy. His phosphatase estimates have followed the clinical course. When bone pain in the region of the neck, shoulder, back and thighs has occurred the dose of estradiol dipropionate, diethylstilbestrol or ethinyl have been increased until control has been accomplished. Today he is comfortable and able to do a few chores on a farm in spite of the metastases which involve his spine and pelvis.

CASE 2.—A man aged 69 with circulatory failure, acute diabetes and obstructive pyuria with nonprotein nitrogen 51 and blood sugar 300, who had been treated by suprapubic cystostomy on Jan. 25, 1940 followed by resection on March 27, had been all right until November 25 (eight months later), when he complained of dysuria but was emptying the bladder. Between Nov. 23 and Dec. 13, 1940 he had nine 1 mg. injections of diethylstilbestrol, which completely relieved his symptoms. On Jan. 23, 1941 he returned complaining of right lumbar pain but voiding comfortably. From that time until now he has had a most interesting course. Castration and removal of his right breast were done on Aug. 11, 1941. The castration was not done because of any difficulty but because of the necessity of getting the injections. The breast was removed to get a microscopic study by Col. J. E. Ash, which was done and reported previously. A typical female breast structure was found. He progressed beautifully after castration in every respect, including relief of the necessity of giving insulin for his diabetes. No more insulin has been necessary to date. Dec. 30, 1942, a little over sixteen months later, he complained of a little backache. From Dec. 30, 1942 until May 17, 1943 his backache was controlled by B complex orally and hypodermic injections of 2 cc. of a multivitamin B preparation from time to time. On May 17, 1943 1 mg. of diethylstilbestrol and 1 cc. of the multivitamin B preparation were given by hypodermic for backache. From that time to date chemicals have been given along with vitamins according to indications. Satisfactory control without narcotics off and on in the hospital have not been possible since March 1944. X-rays have been given in very small doses over the area involved when the patient was complaining of pain along with the chemicals and vitamins between Aug. 11, 1941 and the present time. Irradiation of the pituitary was done by Dr. P. S. Arthur at the rate of 150 roentgens from alternate sides daily beginning March 6, 1944 until 1,500 roentgens had been given. This had no apparent influence on the course of the cancer. The treatment over the painful areas did give

From the Georgetown Medical Urological Service at Gallinger Hospital. Read in the symposium on "The Treatment of Cancer of the Prostate Gland" before the Section on Urology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

relief for a few days at a time. At present his chemical dosage has been built up to 5 mg. of diethylstilbestrol by hypodermic and 0.5 mg. of ethinyl estradiol three times a day, 300 mg. of thiamine hydrochloride and 300 mg. of nicotinic acid amide. His condition is not under control and he is going downhill.

CASE 3.—G., a white man aged 78, Nov. 8, 1940 complained of dysuria, frequency and dribbling. The patient had a large fixed gland. He was given 1 mg. of estradiol dipropionate by hypodermic three times a week without relief, so that on December 14 he had a transurethral resection. From that time until June 1, 1944 he has had diethylstilbestrol by hypodermic injection in 1 mg. doses two or three times a week at varying intervals. He has got along satisfactorily to date.

CASE 4.—M. C., a white man aged 69, had a perineal prostatectomy for cancer ten years previously, followed by incontinence until gradually complete obstruction developed and caused him to learn to catheterize himself twice a day. He was given diethylstilbestrol by hypodermic, 1 mg. three times a week, which resulted not only in ability to void but in a recurrence of incontinence. His residual urine was reduced to 4 ounces (120 cc.). He decided to return to catheterization rather than endure the incontinence. He died of cerebral hemorrhage.

CASE 5.—W. G., a Negro aged 67, on Oct. 17, 1940 had a transurethral resection for an obstructing malignant prostate accompanied by extensive osseous metastases and pain in the back. He was discharged on November 4, to return for x-ray therapy for the pain. He was readmitted on March 3, 1941 with hematuria, dysuria, frequency and a much more extensive prostatic mass. His general condition was very poor. He was given a transfusion and x-ray therapy. He was discharged on March 19 to return for further x-ray therapy. He was readmitted on Oct. 13, 1941 very cachectic, with swelling of the left leg. The phosphatase level was 62 Bodansky units, acid 12, alkaline 150. On Oct. 22, 1941 he had a castration. On October 30 he was discharged feeling pretty well except for slight pain in the left leg. He was readmitted on June 20, 1942 with extreme weakness and backache. The prostate was small. His hemoglobin was 25 per cent. He had several transfusions and was put on diethylstilbestrol, first 1 mg. and then 5 mg. per day, but he went downhill free from pain and died Nov. 4, 1942.

CASE 6.—J. D. J., a white man aged 66, was admitted to the hospital on June 13, 1941 with extensive carcinoma of the prostate and osseous metastases. He had had two previous transurethral resections. He was given 1 mg. of diethylstilbestrol by hypodermic three times a week, which was accompanied by steady improvement. He was castrated on June 20, following which there was no appreciable change in his course. On August 31 he was put on three 1 mg. injections of diethylstilbestrol weekly, from which he improved slowly but steadily until the date of his death on Feb. 15, 1942. The cause of death was lobar pneumonia and the other findings were as follows: Both adrenals were normal in size and there was a 1 cm. metastatic nodule in the right adrenal. The prostate was practically absent, though there were a few malignant cells in the tissue in the region of the prostate.

CASE 7.—V., a Negro aged 60, complained of pain in the back and legs, Dec. 10, 1941. The patient had extensive skeletal metastases and a fixed prostatic mass. He was given 1 mg. of diethylstilbestrol every other day and a high caloric and high vitamin diet with no improvement. On Jan. 16, 1942 castration was performed. Four days later the patient was out of bed, with a good appetite, and no pain or swelling except in the region of the scrotum and penis. He was discharged on February 13 and readmitted on May 20 with pain in the back and general weakness. He was put on a high vitamin and high caloric diet, and on June 14 on 1 mg. of diethylstilbestrol daily for ninety-three consecutive days. He experienced moderate relief from backache, but his general condition went progressively downhill and he died on Aug. 18, 1942. Autopsy revealed the most extensive cancer. The bladder wall was extensively involved. The ribs, lumbar vertebrae, pelvis, liver, both kidneys, both ureters and all of the retroperitoneal lymph glands were involved. The adrenals were about ten times their usual size. The medullary portion was relatively larger in comparison to the cortex than is usually seen. The prostatic mass itself was moderately enlarged.

CASE 8.—P. N., a white man aged 66, when seen on Nov. 15, 1942 presented an extensive rectal growth but no demonstrable metastases. A transurethral resection was done on November 18, and he was discharged on November 25 but was readmitted December 2 on account of hematuria. Five mg. of diethylstilbestrol was injected daily and relieved the hematuria. The patient was discharged on December 19 but returned complaining of hot flashes, which probably for some unaccountable reason were due to the fact that he was taking 15 mg. of diethylstilbestrol instead of 5 daily as he had been instructed. On Dec. 19, 1943 he reported that he had no complaint.

CASE 9.—J. S., a Negro aged 80, had very extensive metastases and a rectal growth with complete obstruction. Resection was performed on Sept. 14, 1942. Despite receipt of 5 mg. of diethylstilbestrol daily, he went down rapidly and died on October 25.

CASE 10.—L. W., a Negro aged 75, was treated by means of resection in March 1942 for an extensive obstructing rectal mass and was discharged on April 7 in fairly good condition. He was readmitted on December 8 with 500 cc. residual urine, no metastases to the bones but pronounced decalcification. On December 20 a resection was performed and he was put on a high caloric and high vitamin diet as well as on 1 mg. of diethylstilbestrol daily. He died on Feb. 1, 1943 of general weakness. There was no other complaint. Autopsy revealed a large prostatic mass shutting off the left kidney and producing a renal abscess. The adrenals were normal grossly and microscopically.

CASE 11.—R. K., a white man aged 60, was admitted with extensive bony metastases and a moderately large rectal mass. Castration was performed on Aug. 4, 1942 and the patient was discharged on August 17 but was readmitted in November 1943 with severe pain in the back. He was given 5 mg. of diethylstilbestrol daily until March 17, 1944. The breasts became so painful that the diethylstilbestrol had to be discontinued. The pain then recurred in the back, and the patient was again put on 5 mg. of diethylstilbestrol. Both breasts were removed surgically on May 19, 1944. Fifteen mg. of diethylstilbestrol had to be given daily in order to control his pain up to the present time. Avitaminosis as demonstrated by the tongue picture has rendered it necessary to administer large doses of vitamin B₁ and nicotinic acid amide. At present he is enjoying sun treatment and is now on an upward course.

CASE 12.—F., a white man aged 57, seen Jan. 10, 1941, had an inoperable carcinoma involving the prostate, bladder and right ureter. Three 1 mg. injections of diethylstilbestrol per week so improved his condition that on April 28, at the urge of the patient's family and physician, radical surgery was decided on. A left ureterostomy was done in which the left ureter was brought out in the left inguinal region. The anatomic and pathologic situation rendered ureterosigmoidostomy impossible. On May 14 the posterior portion of the urethra, the prostate, the bladder and the right lower ureter were removed *en masse*. Following this last operation the patient had the complication of stone production in the left kidney and ureter which called for x-ray investigation. The latter disclosed most extensive osseous involvement, which was not demonstrable at the time of the original examination of the patient. He died on July 4, 1941. The phosphatase was only 2 units (Bodansky).

CASE 13.—R. J., a Negro aged 72, seen March 6, 1943, suffered from complete retention and an extensive inoperable rectal mass. On March 20 prostatic resection was done and 1 mg. of diethylstilbestrol was given orally twice a day. The patient was discharged on April 8 with directions to take 1 mg. of diethylstilbestrol twice daily. On Jan. 12, 1944 there was no difficulty of any kind concerning the cancer and his only difficulty was one of circulation. His phosphatase estimates were not elevated.

CASE 14.—J. McL., a Negro aged 73, seen July 28, 1943, had pain in the back, hips and shoulders. He was emaciated. There were extensive osseous metastases. There was 75 cc. residual urine. On August 10 castration was performed. On August 17 there was complete relief from pain. The patient was put on a high vitamin and high caloric diet and was discharged on September 17. On Jan. 15, 1944 he returned extremely emaciated. The prostatic mass had regressed remarkably. He was given

seven transfusions. On February 23 ethinyl estradiol 0.1 mg. was ordered to be taken daily for a recurrence of his pain. The latter was effectively relieved and he was improving gradually until death occurred suddenly on March 20. Autopsy revealed that the gland was very small, the bones were extensively involved and both adrenals were much smaller than normal, with a preponderance of the medullary portion.

CASE 15.—S., a white man aged 66, seen Oct. 23, 1943, had complete retention of 56 ounces (1.68 liter). The gland was large and fixed. Between the foregoing date and June 1, 1944 the residual urine was decreased to 6 ounces (180 cc.) with diethylstilbestrol and ethinyl estradiol. The dose was 1 mg. of diethylstilbestrol orally daily and 5 mg. by hypodermic weekly up to April 15, 1944. From then until the present the diethylstilbestrol orally has been changed to 0.1 mg. of ethinyl estradiol daily. The dose of 5 mg. of diethylstilbestrol weekly by hypodermic has been continued.

CASE 16.—R., a white woman aged 24, married, seen June 27, 1942, presented extensive inoperable bladder cancer secondary to uterine cancer. She has had the original lesion and metastasis involving the left hip controlled by injections of 10 mg. doses of diethylstilbestrol in conjunction with radiation therapy, and to date the condition is being controlled.

COMMENT

It should be understood that the chemical treatment of carcinoma of the prostate should not be considered as a cure. When the original growth can be completely removed, surgery is unquestionably the procedure of choice in these cases. The chemical treatment should comprise (1) removal of the secreting tissue of the testicles, (2) the introduction of a group of chemical substances into the patient by one of three means—orally, by hypodermic injection or by pellet implantation, (3) a combination of the two preceding methods, (4) nutritional measures and (5) the administration of vitamins according to the appearance of the tongue as described in the foregoing cases.

The chemical substances employed consist of estradiol dipropionate, diethylstilbestrol, ethinyl estradiol and pellets of estradiol benzoate. Apparently all of these substances produce the same effect.

The practical objective of chemical treatment of carcinoma is the modification of the soil in which the malignant cells grow in such a way that their growth will be inhibited. As long as this condition can be maintained, the malignant process is satisfactorily controlled and is thus prevented from damaging the human host.

Dietary measures consist of a high caloric, high vitamin, low cholesterol nutritional intake. The indication for the high caloric, high vitamin diet is to improve the general health of the patient and to increase his resistance. The low cholesterol factor is on account of the observation that high cholesterol diets accelerate the development of cancer and low cholesterol diets decrease the rate of cancer growth.

An interesting observation on the inactivation of estrogenic substances has been made by Zondek, Sulman and Sklow to the effect that estrone is rapidly destroyed by the liver, whereas diethylstilbestrol is very slowly destroyed by the liver. This indicates that the liver is vitally involved in the problem of dosage and action of those substances we are engaged in administering clinically. Obviously the oral administration is less efficacious than hypodermic administration because of the fact that hypodermic injection circulates generally before the liver or other tissue has a chance to destroy it.

The foregoing cases bring up a number of practical considerations: There is no possible way of determining what the nature of response of an individual case will be to the therapy instituted. The dose of the substance used should be the smallest possible amount to accom-

plish satisfactory control. In many instances where castration has ceased to be effective additional control may be accomplished by subsequent administration of the aforementioned chemical substances. There are instances in which extreme metastatic involvement is not accompanied by an elevated phosphatase level. In rare instances the administration of these substances not only does not inhibit the malignant process but apparently stimulates it. Vitamins assist in improving the general condition of patients whose progress is unsatisfactory and to some degree assist in the relief of pain. Irradiation in small doses in conjunction with administration of these chemical substances will control pain to some extent. Irradiation of the pituitary in 1 instance failed to modify favorably the course of the malignant process. Irradiation of the adrenals has not been attempted to date. The procedure which will in most instances insure the most rapid favorable effect on the cancer is castration. The plan for the most prolonged satisfactory control of the malignant process consists of castration and the subsequent symptomatic administration of the aforementioned chemical substances in as small dosage as possible. The human being resents disturbance of biochemical balance, and the smaller the amount of biochemical substances introduced the less will be the biochemical reaction to the administration of these substances. The reaction to these chemical substances is not necessarily proportionate to the amount employed. The course of the group of patients who have been subjected to castration for cancer of the prostate parallels the course of those cases of carcinoma of the breast in which bilateral oophorectomy was performed as practiced by the British in the latter part of the nineteenth century. This procedure was subsequently discarded because of its eventual ineffectiveness and an operative mortality of 6 per cent. A phase of chemical influence of diethylstilbestrol in conjunction with radiation on cancer of the uterus and bladder in a female is difficult to understand, but its administration was instituted in 1 instance because of the favorable experiences of G. G. Binnie with this form of treatment in the case of a young female with uncontrollable metastatic osseous sarcoma. It should be emphasized that this patient was not subjected to this form of treatment until it was felt that the situation was hopeless, as it was, and that anything might be justifiable which offered any chance of benefit. This type of treatment should never be used for patients who are under any degree of satisfactory control. We have 1 patient who presents as close a duplicate to this problem as any one can see to whom we have not dared to give diethylstilbestrol because of the fact that she is being fairly satisfactorily controlled with irradiation and periodic removal of calcified necrotic portions of the bladder and uterus cystoscopically. The cases in which autopsies were obtained failed to demonstrate any uniformity in the condition of the adrenal glands. No opportunity has been afforded up to this time to do autopsies on the pituitary.

CONCLUSION

The chemical treatment of carcinoma of the prostate renders available a relatively simple method for the relief of pain and the varying periods of satisfactory inhibition of extensive malignant processes. While it is realized that the whole chemical problem is but scratched, enough has been observed to stimulate further constructive experimental and clinical efforts in this field.

BREAST CHANGES DUE TO
DIETHYLSTILBESTROLDURING TREATMENT OF CANCER OF
THE PROSTATE GLAND

GORDON F. MOORE, M.D.

CARL A. WATTENBERG, M.D.

AND

D. K. ROSE, M.D.

ST. LOUIS

It has been demonstrated that benign lesions and cancer can be induced in animals by various estrogenic preparations. Lacassagne,¹ Gardner and his co-workers,² Burrows³ and others have shown that treatment of male mice with estrogens gives rise to a higher percentage of breast cancers than would occur normally and at an earlier age.

Lacassagne in 1932 gave weekly injections of estrogens to 5 male mice belonging to a strain in which 72 per cent of females were subject to spontaneous breast

Animals other than the mouse have been employed to show the hormonal mechanisms related to breast cancer. The rat, rarely the host of spontaneous malignant tumors of the breast, also was observed to develop an occasional cancer of the breast if given estrogens. There were also some definite benign lesions which occurred with the giving of estrogens as shown in

Fig. 2.—Breast of same mouse after eighty-five days of estrone treatment.

Fig. 1.—Breast of an adult male mouse with only two small ducts seen in subcutaneous tissue.

cancer, the males not being subject to this development. He then found breast cancer in each of the 5 male mice. Lacassagne presented interval sections of several of these male mice during estrone treatment. The breast of an adult male mouse is shown in figure 1, from Lacassagne's study. The section shows the subcutaneous tissue with only two small ducts with flattened and empty lumen. The breast of the same mouse is shown in figure 2 after having had eighty-five days of estrone treatment. There is an extensive proliferation of the ducts and epithelium present. There is also an active growth of the connective tissue stroma. The breast of this same male mouse is shown in figure 3 after having had one hundred and seventy-nine days of estrone injections. This section shows adenocarcinoma.

Eisen's⁴ experiments. These experiments show the breast changes in male rats treated with estrogens. The initial changes were present in the epithelium and consisted of proliferation, chiefly of the ducts; signs of functional activity of the cells were followed by microscopically visible enlargement of the lumens as a consequence of accumulated secretions. Exhaustion of cellular activity then occurred with subsequent evidence of disintegration of the cells or reversion of the epithelium to a resting stage. Proliferation of the fibrous tissue about cystic ducts was followed by diffuse fibrosis. Figure 4 is taken from Eisen's works and shows the advanced fibrosis of the rat breast tissue, with remnants of enlarged, distorted ducts and contracted epithelial spaces, and the displacement of the fat.

Fig. 3.—Breast of same male mouse after having had one hundred and seventy nine days of estrone injections. Section showing adenocarcinoma.

As the object of our studies is primarily the investigation of breast alterations in the male breast during treatment of prostatic cancer with diethylstilbestrol, these alterations will be described. The breast tissue

biopsy was made before and periodically during administration of estrogens.

Section from an adult male breast before treatment with diethylstilbestrol is shown in figure 5. In this section the interstitial tissue is scarce and there is an occasional duct present in this thin, fibrous stroma, with a few small blood vessels. The epithelial cells of these ducts for the most part are of a single layer, with a thin basement membrane. The epithelial cells are usually large and pale staining, with large nuclei.

After the patient has been treated with diethylstilbestrol, the breast grossly becomes enlarged and often painful. Then as biopsy sections are taken at intervals during treatment, as shown in figure 6 to figure 9 inclusive, some very definite progressive changes take place. Figure 6 is from the same male breast after twelve days of treatment, receiving 240 mg. of diethylstilbestrol, or an average of 20 mg. per day. The same male breast is shown in figure 7 after forty-three days and 705 mg. of diethylstilbestrol, or an average of 16 mg. per day. Figure 8 is a section taken after seventy days, the patient having 1,395 mg. of diethylstilbestrol, or an average of 19 mg. per day. In the section shown in figure 9 we have a decided contrast to figure 5. Figure 9 is the male breast one hundred and twenty days

cells and often a deposition of the fat takes place, as is seen in figure 10, which is a section from another male breast. This patient had treatment four hundred and eighty-five days and had 680 mg. of diethylstilbestrol, or an average of 1.4 mg. per day.

Tissue removed from the prostatic cancer by transurethral resection before treatment with diethylstil-

Fig. 5—Breast tissue from man aged 63 before diethylstilbestrol treatment for carcinoma of prostate gland.

Fig. 4.—Section from male rat breast showing advanced fibrosis with remnants of enlarged distorted ducts and displacement of fat

after treatment, having had 2,145 mg. of diethylstilbestrol, or an average of 17 mg. per day.

During these progressive changes there is a proliferation of the duct epithelium. The cells of the ducts increase in their thickness from one to fifteen or more. Also the ducts become elongated. Then very early in these changes one can find a budding of these ducts. At times six or more buds can be found developing on the one duct which was present before treatment. Along with this duct epithelium proliferation and increase of connective tissue stroma, one also finds considerable edema of all the tissues, especially of the periductal connective tissue. The connective tissue becomes more indistinct in these areas of edema, since the tissue stains pale. There is also an increase in vascularity throughout the connective tissue. The duct epithelium along with its proliferations shows large cells of various shapes and sizes. The duct cells at times are multiplied to such an extent as to occlude the duct. The cells are deep staining and the basement membrane remains intact and not invaded. In none of the ducts can one find secretion if there is any secretory process taking place.

As the connective tissue increases and the amount of interstitial fibrosis is more pronounced, there can develop some flattening of the proliferated epithelial

bestrol showed the same changes as described by Schenken and his co-workers.⁵ The prostate cancer before treatment with diethylstilbestrol showed most of the cells arranged in acini and some forming solid nests or cords of cells. The cell cytoplasm appeared swollen and foamy. The cell nuclei were round and were located in the central portion of the cell, many of the cells showing large, rounded vacuoles.

Fig. 6—Section from same male breast after twelve days and 240 mg of diethylstilbestrol. Average of 20 mg. per day.

The prostatic cancer tissue following treatment with diethylstilbestrol showed a regression of cytoplasm; a large percentage of the nuclei were deep staining and pyknotic, being small and irregular in shape. The pyknotic nuclei were scattered without arrangement

5. Schenken, J. R., Burnes, E. L., and Kahle, P. J.: The Effect of Diethylstilbestrol and Diethylstilbestrol Dipropionate on Carcinoma of the Prostate Gland, *J Urol* 18: 99-112, 1942

In some spaces no nuclei could be found. The nuclear diameter had reduced nearly 50 per cent in most sections since treatment. In the center of many acini, pyknotic nuclei and remnants of cell membranes could be found crowded together without attachment to the periphery of the acini.

These breast changes which have been found are not serious but are dangerous in that the patient often stops taking diethylstilbestrol when the breast pains begin or when they become severe.

Fig. 7.—Same male breast after forty-three days and 705 mg. of diethylstilbestrol. Average of 16 mg. per day.

Fig. 8.—Male breast after seventy days and 1,395 mg. of diethylstilbestrol. Average of 19 mg. per day.

The breast enlargement grossly, as well as breast proliferation microscopically, is no indication as to the amount of benefit the patient is receiving as regards the cancer of the prostate gland. Many patients have very little pain in their breasts and slight microscopic changes, and still the prostate gland, which is cancerous, is reduced greatly in size. The patient is relieved also of his pain and gains weight. Other patients show grossly enlarged and painful breasts, indicative of a chronic cystic mastitis, and well defined breast hyperplasia microscopically, with very little change in the prostatic cancer, or the patient's pain

is not benefited and he does not regain his weight loss. As yet we have had no patient benefit more with orchiectomy than with diethylstilbestrol. That is, if the patient is taking diethylstilbestrol with slight or no benefit and then has an orchiectomy, he has no change

Fig. 9.—Male breast after one hundred and twenty days and total of 2,145 mg. of diethylstilbestrol. Average of 17 mg. per day.

in any noticeable degree. Nevertheless we reserve orchiectomy for those not benefited by endocrine therapy. Such benefits are reported by Huggins.⁶

As yet we have observed no malignant changes in the breast from diethylstilbestrol and rather doubt if they ever will be found. One of the difficulties which still confronts us is the correct dosage of diethylstilbestrol necessary when treating these cancers of the prostate. We have given 60 to 80 mg. per day, but how much of it is excess or waste is not known.

The work of Dr. Huggins is a great advance in medicine. It has had a great deal of comment. Still it

Fig. 10.—Section from another male breast having had four hundred and eighty-five days and 680 mg. of diethylstilbestrol. An average of 1.4 mg. per day. Showing fat deposit and fibrosis.

deserves nothing but appreciation and thanks. There certainly are a large number of prostatic cancer patients who feel that way.

BILATERAL ORCHIECTOMY FOR CARCINOMA OF THE PROSTATE GLAND

CLINICAL EXPERIENCE

JOHN L. EMMETT, M.D.

AND

LAURENCE F. GREENE, M.D.

Member of Section on Urology

ROCHESTER, MINN.

The investigations of Huggins and his associates concerning castration in cases of carcinoma of the prostate gland have been stimulating. The time now has come for members of the medical profession to report their experiences with the procedure in order to assist in its final evaluation as treatment. Although more time is needed to follow patients before all questions can be answered finally, preliminary reports seem justifiable and may be helpful. For this reason we are submitting our experience at the Mayo Clinic up to the present date.

DATA CONCERNING ALL PATIENTS WHO UNDERWENT BILATERAL ORCHIECTOMY FOR CARCINOMA OF THE PROSTATE GLAND

This report deals with 220 patients who received a clinical diagnosis of carcinoma of the prostate gland and who underwent bilateral orchiectomy at the clinic from June 1, 1941 to Dec. 31, 1943 inclusive. Of these patients 62 have returned one or more times since orchiectomy for examination. Information concerning the remainder has been sought by letters of inquiry. We have up to date information on 215 of these patients, and it is on this number that this report will be based. The diagnosis has not been proved by microscopic examination of prostatic tissue in all of these cases, because in some cases only bilateral orchiectomy was performed and an operative procedure was not performed on the prostate gland. Also in a few cases, as is not uncommon following transurethral resection of a prostate gland which is the site of a malignant growth, the tissue obtained for examination was reported to be benign. This of course is due to the fact that the growth involves chiefly the posterior lobe and the resection is not carried deeply enough to encounter it. Nevertheless we feel that there is sufficient clinical evidence concerning all of these 215 cases to justify their being regarded definitely as cases of carcinoma of the prostate gland.

Transurethral resection was performed in 158 of the cases, in addition to orchiectomy. In 115 cases transurethral resection was done at approximately the same time as orchiectomy; in 43 cases several months or years prior to orchiectomy.

Of the 215 patients traced, 163 had clinical, roentgenographic or chemical¹ evidence of metastasis. In 52 cases metastasis could not be demonstrated.

Serum Acid and Alkaline Phosphatase Levels.—When speaking of metastasis as determined by "chemical" means, it is necessary to define our normal values for serum acid and alkaline phosphatase. There has been much discussion in the literature concerning this subject. We have preoperative serum acid and alkaline phosphatase determinations expressed in King-Arm-

strong units per hundred cubic centimeters of serum in 159 cases in this study. In table 1 these values are grouped to show the values for patients who have clinical and roentgenographic evidence of metastasis and those who have not. It will be noticed that Huggins's original values of 3.5 for the upper limit of normal for the serum acid phosphatase seem to be correct rather than 5.0, which is now commonly used. Using 3.5 as the upper limit of normal there are still approximately 35 per cent of false negatives, whereas if 5.0 is considered the upper limit of normal the proportion of false negatives rises to approximately 54 per cent. In the same manner table 1 suggests that the upper limit of normal for the alkaline phosphatase is somewhere between 5.0 and 10.0, which would again substantiate Huggins's original value of 8.0 as the

upper limit of normal. For the purpose of this study we have arbitrarily chosen the values for the upper limits of normal to be 3.5 King-Armstrong units for the acid phosphatase and 10 King-Armstrong units for the alkaline phosphatase. The relationship of the values for acid and alkaline phosphatase is shown in table 2. This table suggests that the importance of the alkaline phosphatase has been minimized in the literature and that probably the level of alkaline phosphatase should carry more diagnostic weight than is accorded it at present.

Survival Rates Following Orchiectomy.—It seems important to decide whether bilateral orchiectomy will increase the length of life of patients who have carcinoma of the prostate. It is too soon to make positive statements in this regard. Nevertheless, attempts to compare mortality rates already have appeared in the literature. In a well followed group of cases of carcinoma of the prostate in which transurethral resec-

1. As shown by determination of the serum acid and alkaline phosphatase levels.

tion was performed at the clinic between the years 1924 and 1937 Thompson² reported that of the total 326 patients 26.2 per cent died within the first year after resection and 50.5 per cent by the end of the second year. Comparative figures for the group of cases that we are reporting in the present paper show that fatalities occurred in 23 per cent within the first year after orchietomy and in only 39.4 per cent by the end of the second year.

These figures require some explanation before any statistical inference is drawn. In the first place the number of cases in our group is of necessity smaller than in the Thompson group owing to the relatively short period during which the operations were done and the short follow-up. For instance, in only 185 of our cases has a year or more elapsed since orchietomy and in only 68 have two or more years elapsed. Also these figures are not entirely fair to the patients on whom orchietomy was performed because the length of life has been computed from the date of the orchietomy. In some of these cases the diagnosis had been made and transurethral resection performed months or years previous to the castration. Another fact which must be taken into consideration is that in the Thompson group little if any selection of cases was made, so that it includes many cases in which the disease was in its early stages and in which no evidence of extension or metastasis was present. Although our series of cases includes a moderate number (52) of patients who had no evidence of metastasis, this proportion would have been greatly increased if castration had been done routinely in all cases of carcinoma of the prostate. In the Thompson series there was no selection of cases as far as the presence or absence of metastasis was concerned. With these factors taken into consideration, therefore, the comparison suggests that in general length of life is prolonged as a result of castration. This subject will be touched on again in the section discussing the patients who had metastasis.

Incidence of Reobstruction Following Transurethral Resection and Orchietomy.—Whether or not orchietomy tends to prevent recurrence of obstructive symptoms after transurethral resection has been a subject

TABLE 3—*Relief from Pain by Orchietomy in 130 Cases of Metastatic Carcinoma of the Prostate Gland*

of considerable interest. During the years 1937 to 1941 inclusive 517 patients who had carcinoma of the prostate gland underwent transurethral resection at the clinic. Twenty-two (4.3 per cent) of these patients returned within the first year with recurrent obstruction demanding further resection, while another 11 patients (2.1 per cent) returned during the second year following resection for the same reason. It is obviously impossible to make an accurate comparison of this group of patients (all of whom have been followed

two years or more) with the series of cases that we are reporting here. From the data available, however, interesting deductions can be made. For instance, of all patients in this group who underwent simultaneous transurethral resection and orchietomy none returned within the first year with reobstruction. (One hundred and eighty-five patients have been followed one year or more since orchietomy.) Only 1 such patient has returned for subsequent resection. This patient returned

sixteen months after orchietomy. One patient on whom only orchietomy was done returned seventeen months later for transurethral resection. Four other patients in this series returned for transurethral resection, but in all of the 4 cases the original prostatic operation had been performed many months previous to the orchietomy. In all of them the time interval between the original prostatic operation and subsequent transurethral resection was more than two years. These figures suggest that there must be a definite retardation of the rate of the local growth following orchietomy.

Results of Orchietomy in Cases in Which Metastasis Occurred.—Of the 215 traced patients in this study, 163 had evidence of metastasis as determined clinically, roentgenographically or chemically (by means of serum phosphatase levels). In a study of this kind, in which it is necessary to rely principally on follow-up letters from patients to determine the course of the disease, one must choose data which are least open to error of interpretation. By far the outstanding clinical evidence of metastasis is pain, and for this reason we have chosen this symptom as the prime indication of the course of the disease. In an effort to keep our data as accurate as possible, in our most recent follow-up letter we asked the patients who had suffered from pain prior to orchietomy to state in percentage form the degree of relief that they secured within the first few weeks after orchietomy. From their answers we have corrected the data on our records where indicated.

Of the 163 patients who had metastasis, 130 had complained of pain prior to orchietomy. Table 3 shows the degree of relief that these patients secured from the operation; the results are classified further on the basis of the degree of malignancy of the prostate according to Broders' grading (where those data are available). It will be noticed that 60 of the 130 patients (46 per cent) secured complete relief and that another 22 patients were greatly improved. This suggests that, in more than 60 per cent of cases in which there was pain due to metastasis, great immediate relief can be expected if orchietomy is performed. It is also suggested from table 3 that the degree of malignancy is not a factor in the immediate results obtained.

² Thompson, G. J. Transurethral Resection of Malignant Lesions of the Prostate Gland, J. A. M. A. 120: 1105-1109 (Dec. 5) 1942

The next important factor is the length of time these patients are relieved of their pain and whether the relief is permanent in any cases. To secure this information we have compiled in table 4 data from the 60 patients who obtained 100 per cent immediate relief following orchiectomy. In approximately half of these cases the pain has recurred, the length of relief varying from four to eighteen months, the largest group of cases falling into the seven to twelve month period. Information regarding the 32 patients who are still relieved of their pain is compiled in table 5. The most interesting observation here is that 13 patients have remained free from pain for more than eighteen months. In 8 of these 13 cases the grade of the lesion was known. Six lesions were of a high grade of malignancy (grade 3 or 4). These data, though of interest, comprise too few cases to enable one to draw any conclusions regarding the relationship of the grade of the tumor to the length of relief to be expected from orchiectomy.

Results of Orchiectomy in Cases in Which Metastasis Did Not Occur.—This part of the problem is at present the most important to be settled as far as therapeutics is concerned. Should orchiectomy be done as a prophylactic measure when metastasis cannot be demonstrated or should it be done only to relieve symptoms from metastasis? In this study we have 52 patients who were without demonstrable evidence of metastasis at the time when bilateral orchiectomy was performed. Data concerning this group of patients are given in table 6. In evaluating this table it should be borne in mind that it is not always possible to demonstrate the presence of metastasis, so that some of these patients no doubt had suffered from metastasis prior to orchiectomy. Of these 52 patients, 35 per cent have already shown signs of metastasis and 15 per cent are dead. More cases and a longer follow-up will be necessary before one can draw accurate conclusions.

Obstruction of the Vesical Neck.—Will bilateral orchiectomy effect enough regression of the local growth to relieve urinary obstruction and thereby obviate the

TABLE 5.—Interval of Time Since Orchiectomy Correlated with Malignancy in 32 Cases in Which Metastatic Pain Is Still Absent

necessity of operation on the vesical neck? In this series 62 patients underwent orchiectomy alone. All others underwent transurethral resection either at the same time or at some previous time. Of these 62 patients, 24 suffered from definite obstructive symptoms. Seventeen of these 24 patients (71 per cent) experienced definite improvement. The remainder did not obtain any relief of symptoms.

Regression of Local Growth.—Only 62 of our patients have returned for reexamination. It is very difficult to make an accurate statement concerning the size and

consistency of the prostate, as many variable factors are present. Some patients had a transurethral resection while others did not. Some patients were examined by different consultants on their return. At best it is difficult from one's notes to decide whether minor degrees of change have occurred. Evaluating these data as honestly as possible, we obtained the following results: Of 47 cases in which there were sufficient data

TABLE 6.—Incidence of Occurrence of Metastasis and Length of Life After Orchiectomy in 52 Cases in Which There Was No Evidence of Metastasis at Time of Operation

in the records for evaluation, 5 showed such definite regression that it would have been impossible from digital rectal examination to make a diagnosis of carcinoma of the prostate. Ten more showed definite regression, while in the remaining 32 no change could be demonstrated.

Roentgenographic Evidence of Metastasis.—Of the 62 patients who have returned for reexamination there was roentgenographic evidence of metastasis prior to orchiectomy in 45. In only 6 of these was improvement noted in subsequent roentgenographic study. In 3 of these cases, however, there was a complete disappearance of the metastatic lesion in the bone. In 7 cases in which metastasis could not be demonstrated roentgenographically prior to orchiectomy it appeared after orchiectomy.

Paralysis and Pathologic Fracture.—We have encountered in this series 1 case in which pathologic fracture of the femur healed spontaneously after orchiectomy. One patient entered the hospital suffering from complete paralysis of the lower extremities from metastasis to the spinal cord. There was no improvement after orchiectomy and the patient died within two months. In another case paralysis developed thirty-six hours after orchiectomy. Follow-up letters disclose the fact that in 4 more cases paralysis has developed since orchiectomy. In 2 of these cases it occurred within nine months, in 1 within five months, and in 1 within a "few" months after orchiectomy.

DATA CONCERNING A "CLOSED" GROUP OF PATIENTS WHO HAVE BEEN FOLLOWED EIGHTEEN MONTHS OR MORE SINCE ORCHIECTOMY

We have selected from the entire group of 215 patients those on whom orchiectomy was done prior to November 1942. As of May 1, 1944 (the date of our most recent inquiry) this yields a group of 133 patients on whom orchiectomy had been done eighteen months or more previously. We are reporting these patients here as a "closed" group of patients and shall make additional reports on this group from time to time. We believe that this may be a more accurate method of the final evaluation of this problem than analysis of

results for a group less homogeneous with respect to length of observation since orchiectomy.

Of the 133 patients in the "closed" group 96 showed evidence of metastasis prior to operation, while in 37 no metastasis could be demonstrated. Fifty-nine of these patients are already dead (table 7). It will be

noticed that 21 (22 per cent) of the patients who showed evidence of metastasis died within the first nine months after operation. In other words, 78 per cent survived the first nine months as compared with 33 per cent in Bumpus's³ series. This survival rate is almost identical with that given by Nesbit and Cummings⁴ in their "closed" series of cases.

Of the 96 patients who gave evidence of metastasis, 78 had pain prior to operation. The degree of relief following operation is shown in table 8. Thirty-three of the patients secured 100 per cent relief of pain, while another 13 patients were greatly improved, making a total of 59 per cent who secured definite immediate relief. As in the data given previously for the entire group, there seems to be no correlation between the grade of the tumor and the immediate response to castration. The length of time the patients were relieved of pain is shown in table 9. It corresponds roughly to that of the large group, the majority of patients falling into the seven to twelve month period. In table 10 is a summary of data on the 13 patients of this group who are still relieved of pain, all of them being followed longer than eighteen months. As mentioned previously, there seems to be no correlation between the grade of malignancy and the length of relief, although it can be said that the lesions of higher grades seem to respond as well as, if not better than, those of the lower grades.

ESTROGENIC THERAPY

Our experience with treatment by means of estrogens in this disease has not been sufficiently well studied yet to allow us to make any positive statements regarding its efficacy. It has been our impression that orchiectomy yields more dramatic and immediate results than estrogenic therapy. Occasionally, however, a most brilliant result is achieved with diethylstilbestrol. We have encountered several cases in which orchiectomy has given relief when estrogenic therapy had failed. We have also encountered a few cases in which estrogens have seemed to give relief from pain after orchiectomy had failed. These cases have not been striking, however, and the results were not dramatic. We are at present in the process of trying to evaluate more accurately our results with estrogenic therapy.

CONCLUSIONS

The indication for bilateral orchiectomy is carcinoma of the prostate with metastasis. Bilateral orchiectomy is especially efficacious when the metastatic growths have given rise to symptoms. The period of relief following orchiectomy varies from months to years. Whether any patients will remain permanently relieved seems extremely doubtful. Apparently the large majority of patients have a recurrence of symptoms within a year. Whether or not "prophylactic" orchiectomy (done in the early stages of the disease before metastasis has appeared) measurably influences the course of the dis-

case is not yet known. This problem cannot be settled until more time has elapsed and a larger series of cases in which "prophylactic" orchiectomy has been performed has been studied. Until this problem has been definitely settled, our present practice is to advise orchiectomy primarily for patients suffering from metastasis, for the relief of metastatic symptoms. Results to date suggest that when orchiectomy is performed in

conjunction with transurethral resection the frequency of recurrent obstructive symptoms requiring subsequent prostatic resection is reduced; furthermore, if such symptoms do appear the time interval between resections is increased. We are also treating a group of patients who do not show evidence of metastasis with estrogens after transurethral resection to see if the course of the disease can be appreciably altered over a substantial period. We are interested to know whether preliminary estrogenic therapy in such cases will tend to nullify the palliative effects of castration if the latter should become necessary for the control of symptoms later on.

EXPERIENCE WITH ORCHIECTOMY FOR CARCINOMA OF THE PROSTATE

H. C. BUMPUS JR., M.D.
BEN D. MASSEY, M.D.
AND
EARL F. NATION, M.D.
PASADENA, CALIF.

The wave of enthusiasm for performing orchiectomy in the treatment of carcinoma of the prostate seems to have passed its crest. As experience has accumulated and patients have been observed for longer periods of time it has become apparent that the beneficial early effects, so eagerly reported at first, are not the whole story. Some writers are now questioning the advisability of routinely performing orchiectomy for carcinoma of the prostate and others are denouncing the operation. However, its fate probably will not be the limbo to which orchiectomy for benign prostatic enlargement was finally relegated at the turn of the century. The disillusionment caused by the discovery that there has not been found, after all, a cure for cancer of the prostate should not cause the too hasty repudiation of a procedure which offers some help, where there was so little hope before. The palliation affected by the operation is too striking and obvious to permit its abandonment. It remains, rather, to determine in which cases and at what stage of the disease orchiectomy should be employed and when estrogenic hormone therapy may be substituted or used to supplement the operation. It is essential, therefore, that as many cases be studied and reported as possible, even in small series such as the present one, that these problems may be solved soon by cumulative experience.

RESULTS OF ORCHIECTOMY

Twenty-five patients with carcinoma of the prostate on whom bilateral orchiectomy was performed in private practice between July 1941 and December 1943 form the basis for this report. As private patients can be followed more closely than those treated in large charity institutions, more exact information may often be gained from fewer cases. Included in the group are the 6 cases previously reported by one of us.¹ The majority of patients were given diethylstilbestrol in doses of 1 to 3 mg. daily after orchiectomy.

The age distribution of the patients was as follows: sixth decade of life, 3; seventh decade, 12; eighth decade, 9; ninth decade, 1.

All the patients, with 1 exception, showed decided improvement following the operation. This improvement consisted of such changes as increased vigor, strength, weight and appetite, a sense of well-being, cessation of pain and diminished urinary difficulty. The 1 patient who was not improved remained about the same for six months before beginning to grow worse. He was alive thirteen months after orchiectomy, his metastases progressing and his health failing.

Five of the 25 patients (20 per cent) have had definite recurrence of their symptoms, 4 after twelve to sixteen months' remission and 1 after six months. Three of these patients have already died. Two other patients have died of causes unrelated to their carcinomas, eighteen and fifteen months after orchiectomy. Neither patient had had recurrence of pain or other symptoms referable to his prostatic carcinoma.

Seventeen patients (68 per cent) are alive and apparently not suffering from activity of their carcinoma.

Three of the 4 patients (75 per cent) operated on two years ago or more are alive and well, one thirty months after orchiectomy. The malignancy in 2 of these cases was grade 3. One of the 3 had extensive pulmonary metastases which receded after orchiectomy. The fourth is failing rapidly twenty-nine months after operation. The tissue in this case was also grade 3 malignancy. Of the 11 patients operated on between one and two years ago 5 (46 per cent) are dead, 3 of carcinoma and 2 of other causes. One received no benefit. Four (36 per cent) are well and 1 relapsed after twelve months' relief. All of the 10 patients operated on within the past year remain free of symptoms of advancing malignancy.

Tissue from the prostate was available for microscopic examination in 15 cases. These were graded as follows: grade 2, 6; grade 3, 7; grade 4, 2. All the patients whose tissues were graded 2 are alive and free from symptoms of malignant activity, one thirty months after surgery. Two of those graded 3 relapsed, one sixteen and the other thirteen months after orchiectomy. The second of these died two years after his operation, while the other is still alive. Of the 2 patients with grade 4 malignancy, 1 is living and well fourteen months after surgery; the other died eighteen months following operation of other causes than malignancy.

There was considerable variation in the length of time required for softening of the prostate after orchiectomy and diethylstilbestrol. There seemed to be no correlation between the length of the interval and the grade of malignancy. Rapid softening, while usually a favorable sign, occurred in 2 patients who died following recurrence of symptoms, 1 six and the other thirteen months after orchiectomy.

The testes from our patients were not weighed, as suggested by Huggins,² but were examined microscopically. There was no discernible correlation between the microscopic appearance of the testes and the degree of relief obtained.

One factor which has not been given adequate consideration in some studies is the removal of urinary obstruction. Transient improvement may follow improved urinary drainage alone. Thirteen of the patients considered here had transurethral prostatic resection in addition to orchiectomy. Twelve had no surgical procedures other than orchiectomy. Only 1

2. Huggins, C.: Effect of Orchiectomy and Irradiation on Cancer of the Prostate, *Ann. Surg.* 115: 1192, 1942.

of the 5 patients who had relapse of symptoms had required prostatic resection. Twelve of the 19 patients not having relapse required transurethral resection in addition to orchiectomy. (In those cases in which tissue was not removed the diagnosis was made by the usual means, including roentgenography and phosphatase determinations.) Improvement was no more consistent or striking in those patients who had transurethral resection than in those having orchiectomy alone, except that symptoms of obstruction were relieved more promptly in the former patients.

The psychic improvement that some of these patients undergo immediately after castration has not been emphasized sufficiently in the literature. One of our patients, alive nearly a year after his orchiectomy, is a striking example of the change in mental outlook produced by castration. When first seen in consultation he was extremely apathetic, responded sluggishly to questioning and didn't give any evidence of caring whether he was castrated or not. He had no regard for his personal appearance. His bed clothing was covered with the usual amount of tobacco juice and soup stains seen in this type of case. He showed absolutely no interest in the daily news or his surroundings. In contrast, the day after his castration he was eagerly demanding the early delivery of the morning papers and responded readily to all questions. A few weeks after his dismissal from the hospital his family physician asked whether the striking mental improvement had been reported in the literature. He stated that, while his patient had formerly cared nothing about his personal appearance or exhibited the slightest interest in the little niceties of social intercourse, he now greeted him most effusively at the time of his professional visits, graciously proffering him a chair. His clothes, formerly spotted and rumpled, were now pressed and clean. A transurethral resection had not been done in this case, so that these improvements cannot be attributed to improved urinary elimination; nor had estrogenic therapy been instituted to confuse the picture.

COMMENT

It is becoming apparent that all patients with prostatic cancer will eventually have a relapse of symptoms if they live long enough following orchiectomy. It is not yet possible to predict accurately the percentage of patients who will survive beyond the average expectancy, which is about thirty-one months after the diagnosis is made.³ We agree with Nesbit and Cummings⁴ that no criteria have been found for predicting the prognosis in any case.

Since prostatic cancer is not cured by orchiectomy and estrogenic hormones, it is essential that the best means of control be determined. There remains no doubt that temporary control is possible.

Crane and Rosenbloom,⁵ in an analysis of 340 cases of cancer of the prostate seen at the Los Angeles County General Hospital from July 1, 1938 to Jan. 1, 1944, report that simple drainage or transurethral resection, or endocrine therapy alone did not produce such satisfactory improvement as when combined with cas-

tration. In their series of cases the survival time was longest for the patients who had received all three forms of treatment in combination.

It is sometimes argued that, in view of the fact that one is dealing with a hopeless malignant process, all methods of combating it should be employed with the least possible delay. If, by this combined therapy, it were possible to cure the disease, such an argument would be logical. However, since all forms of therapy to date have proved only palliative, the prolongation of such treatment seems preferable to its immediate total application. With the patients who are the subjects of this report one wonders whether, if they had been treated by estrogenic substance alone until such evidence of advance of the cancer as pain and cachexia had occurred, castration would then have given the same spectacular results produced by orchiectomy prior to the administration of endocrine therapy. A few reported cases of relief of recurrent symptoms by estrogens after orchiectomy, and by orchiectomy after preliminary estrogens, suggest the possibility that these two weapons should be saved and used separately and in succession, rather than in conjunction, to afford the patient the greatest relief.

The effect of orchiectomy following preliminary estrogenic therapy might not be as dramatic as primary orchiectomy but might prolong life and the period of relief. Since Huggins's² early reports it has been thought that estrogenic hormones alone would not suffice. Recent reports contradict this.⁶ We have been favorably impressed by our results in a number of cases so treated. We have 3 patients who remain well after over two years treatment with diethylstilbestrol alone, in doses of 1 to 2 mg. daily.

Nesbit and Cummings⁴ conclusion seems to be a logical one "that the maximum benefit to the patient may be derived by delaying endocrine treatment until indicated by the onset of symptoms arising from advanced or metastatic lesions." It is to be hoped that this will assure the patient the maximum period of comfort as well as prolong his life. Whether such treatment will require orchiectomy or whether estrogenic hormone therapy will suffice remain moot questions.

CONCLUSIONS

The results of orchiectomy in 25 cases of carcinoma of the prostate confirm the impression that temporary relief accrues to almost all patients. Forty per cent of our patients who have been observed for a year or more following orchiectomy have had recurrence of symptoms. It is to be anticipated that they will all eventually relapse.

It therefore remains to regulate better our use of orchiectomy and estrogens. They probably should be delayed until symptoms of an advanced malignant condition are manifest, then be used separately and in succession rather than in conjunction.

SURGICAL REMOVAL OF CANCER OF
THE PROSTATE GLAND

THE RADICAL OPERATION

J. A. CAMPBELL COLSTON, M.D.
BALTIMORE

For the study of the ultimate results of any surgical procedure a thorough knowledge of the disease for which the operation is performed is essential, especially the course of the particular disease when uninfluenced by treatment. In any pathologic process there are numerous variables encountered, and in no type of disease is this so true as in cancer. Great variations occur in the rapidity of growth of the original neoplasm as the result of differences in the biologic activity of the individual cells as well as their tendency to invade the lymphatics or the blood stream. It is obvious, therefore, that only by a detailed study of long series of cases can a true picture of the disease be obtained, so that when a diagnosis of this particular disease has once been made the physician is able to prognosticate with a reasonable degree of accuracy the course which the disease will follow.

In carcinoma of the prostate great differences in the progress of individual cases have long been known. On the one hand there occur cases in which growth of the malignant cells is extremely rapid, with no apparent inhibition from the tissues of the host, so that invasion of the lymphatics occurs early and death may result from generalized carcinomatosis in the course of a few months. On the other hand there are the numerous cases recorded which have been observed over periods of ten years or even more with only minimal extension of the disease, but these instances are exceptions at opposite poles of the whole picture, and somewhere between them can be plotted the course of the vast majority of the cases of carcinoma of the prostate.

The invaluable studies of Bumpus¹ on the large series of cases which were available to him have given us a very clear understanding of the course which the usual case of cancer of the prostate may be expected to follow. He found in his series of untreated cases that the average duration of life from the onset of the first symptoms was approximately thirty-one months. When metastasis was found at the time of the first examination 66 per cent of the patients died within nine months, and when metastasis was not found the average length of survival was one year. Hager and Hoffmann,² in a study of another long series of patients, found that 47 per cent died within a year after the diagnosis was made. By careful studies such as these we are now able to predict with considerable accuracy what may be expected in the prognosis of the usual case of cancer of the prostate, with due reservations for the exceptional ones.

Of greatest importance in the study of any disease is a thorough knowledge of its pathologic anatomy. This aspect of carcinoma of the prostate has been

exhaustively examined, and the work of Rich,³ Moore⁴ and many others has resulted in a very clear understanding of the disease. The majority of workers in this field are in agreement that the disease begins in the posterior lobe in over 75 per cent of cases, that it invades the remaining portions of the gland slowly, and that its extension through the capsule is prevented by the two tough layers of Denonvilliers' fascia which are devoid of lymphatics. By gradual and usually slow progress the bases of the seminal vesicles are invaded and finally the perineural lymphatics become involved, which ultimately results in metastasis to the regional lymph glands and then to bones, particularly those of the pelvis and the lumbar vertebrae. Therefore in every case of cancer of the prostate there is a stage in the progress of the disease in which complete surgical excision of the entire neoplastic process is practicable before extension through the capsule or into other nearby structures has occurred. It was on the basis of this sound and irrefutable reasoning that Young⁵ devised the technic of his radical perineal prostatectomy.

With a knowledge of the pathologic anatomy of the disease, it is obvious that symptoms of urinary obstruction will not occur in the early stages unless a coincident benign hyperplasia is present. Thus it is apparent that the diagnosis of carcinoma of the prostate at a time when complete surgical excision of the entire disease is feasible must be made by careful rectal examination, during which evidences of nodules or areas of localized, stony hard induration are encountered.

The clinical criteria for cases in which complete removal of the disease is surgically possible have been previously discussed, but a repetition at this time would seem appropriate. 1. The neoplasm, on rectal palpation, must not extend through the capsule of the gland, into the membranous urethra or beyond the bases of the seminal vesicles, and the gland must be freely movable because fixation indicates the spread of the disease into the periprostatic tissues. 2. Evidences of metastasis must be excluded by careful physical examination, and particularly by x-ray studies. The acid phosphatase determinations should be within normal limits, although in the absence of x-ray evidence of bone metastasis an elevation of acid phosphatase seldom if ever will be encountered. 3. The patient should be a good surgical risk and have a good life expectancy. It is questionable whether the operation should be performed on patients in the eighth or ninth decades of life. It is a well known fact that the mortality of any surgical procedure increases with age, and the many statistics which have been published on various operative procedures for the relief of benign prostatic hypertrophy amply substantiates this point. Also it is well known that in older persons cancer of the prostate, generally speaking, progresses more slowly, probably because of the diminished androgen stimulation which occurs in the later decades. The question of age, however, can never be a hard and fast rule, because individual patients present so many variations. The appraisal of the physical condition of the patient and, in a general way, his ability

an untreated series of early cases which might be compared with the observations which we have recorded. However, Thompson⁹ has reported a series of 337 cases treated by transurethral resection prior to 1937. He records a five year survival rate of 14.1 per cent, with several patients living eight or nine years. It must be emphasized that these statistics can in no sense be compared with those herein presented, for in a large majority of Thompson's cases the disease must have been far too extensive for complete radical excision.

The postoperative course of patients who survived the radical operation, regardless of whether the disease recurred, is in striking contrast to series of cases in which purely palliative procedures were employed to relieve the obstruction. Thompson⁹ reports that urinary obstruction recurred and two or more operations were necessary in 25 per cent of his cases. The high incidence of persistent infection with frequency, urgency and hematuria which is encountered following transurethral resection for malignant disease is familiar to all urologists. G. G. Smith¹⁰ has recorded his impression that the postoperative course of patients subjected to the radical operation is far better than patients treated by palliative procedures in that recurrence of obstruction rarely occurs, and for this reason he has advocated the radical operation in cases in which the prognosis for complete removal of the neoplasm is poor or even hopeless. He feels that the removal of the main mass of malignant disease protects the patient against later recurrence of obstruction and that portions of cancer which it may not be possible to remove remain in areas high up between the bladder and the rectum, where they usually grow very slowly and cause no interference with urinary function. The present study entirely substantiates this point of view. In 4 cases urinary obstruction is recorded as having occurred at varying intervals of time after the operation; this was controlled by simple dilation of a stricture at the operative site. One patient (the first patient operated on, in 1904) died nine months after operation from urinary obstruction, perineal abscess and sepsis, probably resulting from a stricture. Another patient died from instrumental rupture of the bladder following attempts to dilate an obstruction which occurred as a result of recurrence of malignant disease at the neck of the bladder. In another case a transurethral resection was necessary to relieve urinary obstruction caused by recurrence of the cancer. Thus in only 2 cases in this series did urinary obstruction recur to such a degree that operative measures were necessary.

In the foregoing the salient points of our knowledge concerning the origin and extension of carcinoma of the prostate have been reviewed, and the fact that the disease in its earliest stages is readily amenable to complete surgical eradication has been stressed. The importance of early diagnosis, as in all other types of malignant disease, is self evident. The criteria for cases suitable for the radical operation have been presented, and it has been shown that with careful examination and education of the profession it is possible to find among all patients admitted to the hospital for cancer of the prostate 20 per cent in whom the radical operation

can be carried out with a reasonable prospect of cure. The all too prevalent tendency to wait for the development of obstructive symptoms in early cases of the disease has been condemned, because by this policy of watchful waiting the possibility of a permanent cure is denied these patients. The important question of endocrine therapy has not been discussed because all the patients who are included in this study were operated on before Huggins¹¹ presented his fundamental work on this subject.

From 1904, when Young carried out his first radical perineal prostatectomy for carcinoma, until 1939, eighty-seven similar operations have been performed in the Brady Urological Institute with a mortality of 5.8 per cent—a figure which certainly compares favorably with operations undertaken in other deep parts of the body designed for the total eradication of malignant disease. Of the patients who left the hospital following operation there was a five year survival rate of approximately 50 per cent, a figure about the same as has been previously reported by Young, Lewis⁶ and Smith.¹⁰ If the patients who died within a period of five years after operation without evidence of recurrence or metastasis are eliminated, the five year survival rate is 56.5 per cent.

Cancer of the prostate is a very common disease and can be recognized in its early stages by rectal palpation. When the diagnosis has been made before the neoplasm has advanced too far, total extirpation by radical surgery is possible.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. HERBST, DRs. MOORE, WATTENBERG AND ROSE, DRs. EMMETT AND GREENE, DRs. BUMPUS, MASSEY AND NATION AND DR. COLSTON

DR. ROBERT H. CUMMINGS, Ann Arbor, Mich.: Already one begins to detect a trend to utilize castration in cases of advanced carcinoma of the prostate in which symptoms of metastasis are present. It is in this type of case that the subjective response is so brilliant. Relief of pain appearing immediately after bilateral orchiectomy in 88 per cent of our series of cases in which that symptom was present prior to castration is a somewhat higher percentage than that reported today. The objective changes following institution of this form of endocrine therapy in these same advanced cases is likewise often brilliant. Definite regressive changes in the primary neoplasm occurred in 32 per cent of Dr. Emmett's cases and in 34 per cent of Dr. Nesbit's and mine. Some degree of regression in size of the prostate was thought to have occurred in 66 per cent of our cases. Seventy-one per cent of Dr. Emmett's patients experienced definite evidence of improved urinary function following bilateral orchiectomy alone. In our series 9 of 14 patients who had no operation for the relief of prostatic obstruction experienced more normal urination following castration. In the group of patients with metastases, 78 per cent of Dr. Emmett's and 84 per cent of our patients survived the nine month period shown by Dr. Bumpus in a similar group of patients in whom endocrine therapy was not used, to be associated with only 33 per cent survival over an equal period of time. These few illustrative comparisons seem to us too to demonstrate the efficacy of castration when prostatic cancer has metastasized. This therapeutic procedure has been followed by an average remission of carcinogenic activity for 11.4 months in delayed failure cases. The fact that metastases occurred in 35 per cent of Dr. Emmett's cases in which none were detected prior to castration, together with the fact that 15 per cent of these patients died, suggests that this procedure does not constitute prophylaxis against extension of this neoplasm. In our experience 18.8 per cent developed metastases and 12.5 per cent died

not less than twenty-one months after bilateral orchiectomy. Now we are at present using endocrine therapy in an effort to prevent extension, feeling that to do so voids our hand of trump cards to play if and when the patient requires relief from his suffering.

DR WAITER M. KERN, Milwaukee. The papers of Dr Herbst and Drs Bumpus, Massy and Nation demonstrate that the salutary effects of castration and of estrogens are less enduring than had been hoped for previously. Evidence points to the generalization that, if one method fails, substitution or combination with the other method will also fail. Not one castration has been carried out in my series of 78 patients because it seemed desirable to attain as large a number as possible, employing a single method, in order to reach a proper appraisal of that method. Simple estrogenic treatment will gain in favor, because all of the attainable benefits of castration minus some of its undesirable side effects are obtainable by the judicious use of the true hormone estradiol given to each individual patient by the most effective route. The changes produced by estrogens, which so abruptly alter the blood picture and clinical course of the disease are unquestionable evidence of their profound influence. Of 42 private patients who have been followed, approximately 60 per cent have been definitely benefited for periods exceeding six months. During the past year 3 patients who had been greatly benefited and were apparently stabilized under treatment with estradiol lost ground in spite of increased dosage and died. Fifteen patients presented themselves with definite indications for surgical intervention because of urinary obstruction. Through the prompt application of estrogenic therapy, urinary antiseptics and the use of continuous or intermittent catheterization, they have obtained improvement in general health, shrinkage in the prostate and ability to empty the bladder with little or no residual urine. Of these 15 patients, 4 have died, 2 of carcinoma and 2 of intercurrent disease. In no instance did significant amounts of urinary retention recur. The blood sedimentation rate as an aid in diagnosis and an indicator of the progress of the disease has proved very helpful. Approximately 85 per cent of the patients will show a deviation from normal, and this gives it a much wider range of usefulness than estimations of the blood phosphatase levels. My preference for nonsurgical treatment is based on several considerations. From the standpoint of economy, the evidence is overwhelmingly in favor of the nonoperative treatment. The hospital expense for the average patient would purchase a supply of estradiol sufficient to last two years. The operative fee no doubt would purchase a number of added years' supply carrying well beyond the life expectancy of men in this age group. It is not unlikely that estrogens actually bring about more thorough emasculation than castration. The estrogen, through anterior pituitary gland depression, not only suppresses testicular function, causing shrinkage of the testicle and prostate and absolute impotence, but also possibly depresses the andromimetic function (or testicle imitating function) of the adrenal cortex. Over the course of more than three years, several of my carcinomatous patients were maintained in good health with small dosage of estradiol 0.05 mg twice daily, without need of increments. It is my impression that an inadequate dosage may be ineffective but that when an adequate dose is established further increments are ineffective.

DR A. ELMER BELT, Los Angeles. The group of patients on whom I operated perineally seemed to do better than those operated on electrosurgically or by the punch operations, because the cauterized urethra and bladder neck after the punch operation were painful. These studies in castration and administration of diethylstilbestrol presented here reveal an inability on the part of the compilers of their data to come to definite conclusions as to the end result. Since the work was in its initial stages dependent on experimental work, let us turn again to the experimental work to see what correlated effects not discernible clinically are revealed in experimental animals. Castration produces a hypertrophy of the anterior pituitary, experimenters are uniform in telling us, with the formation of certain large clear cells always recognizable as due to castration. This

increase in pituitary size indirectly affects the thyroid, causing the thyroid to hypertrophy, and it is thought to cause a like effect on the adrenal. It is not definitely known that it does cause an effect on the adrenal. All of these glands—the adrenal, the pituitary and the thyroid—are prevented from undergoing these changes with the administration of androgens, either female or male. An example is the fact that the female estrogen prevents hot flashes in these men with castration. Therefore why not give the harmless and helpful female hormone at once and continuously after castration? It seems especially logical to follow this lead along the road of known physiologic effects rather than flounder in the maze of clinical data which so far cannot clearly be interpreted. In our clinic, if a radical operation is possible we perform it. If the operative results at the time of the radical operation show carcinoma remaining, an orchiectomy is done at once and diethylstilbestrol is given as soon as the patient is stable after operation and, if extensive carcinoma is encountered, orchiectomy plus diethylstilbestrol plus resection if there is obstruction of urine is carried out. In the 340 cases reported by J. J. Crane from the County Hospital, that method of following up with transurethral resection, castration and the administration of diethylstilbestrol gave those men their best results.

DR N. G. ALCOCK, Iowa City. Slides of a patient with bone metastasis due to carcinoma of the prostate demonstrated that practically all x-ray evidence of the metastases disappeared on the administration of diethylstilbestrol. A few others showed definite evidence of decrease in the metastatic lesions. I am confused and discouraged in the matter of treatment of cancer of the prostate. I am not optimistic in regard to the surgical treatment. A lesion to be amenable to surgical treatment must have certain characteristics. To be eliminated it must be so located that one can get far out around it. The aim of all treatment of cancer should be just one thing, and that is cure. The patient is either cured or he is not cured. A patient who has a recurrence of cancer ten years after treatment is no more cured than the one who has recurrence in six months. We all agree that the only cured cases of carcinoma of the prostate come about through surgery, but surgery is applicable to such a tremendously small percentage of the cases that it cannot be the answer to the whole problem. I doubt if the surgical possibilities will be extended further than they are at present either by greater perfection of technique or by earlier diagnosis of the condition. No one has ever claimed that either orchiectomy or diethylstilbestrol brings about a cure and in that respect we are all disappointed. I hope that with further study we may get something that will be the answer. Certainly orchiectomy and diethylstilbestrol at the present time do not make the answer, but they may lead to the answer. That, to me, is the bright ray of hope.

DR VICTOR LISPINSKY, Chicago. Dr Herbst laid great emphasis on the high caloric diet and the high vitamin content of that diet. It is generally considered that that type of diet is protective against bacterial infection, but it is just the opposite for virus infections. What that has to do with the life of the cancer cell, of course, we don't know, but it is at least debatable or should provoke thought that we may not be doing our patient as much good by giving him a very high diet. If we give him just a sufficient diet, he might do just as well and his cancer might not be able to grow so fast. Of course, prostatic cancer is a specialistic cell that is dependent for its growth and its activity to a large extent on the testicular androgens, and that is the factor on which our whole theory of female sex hormone therapy is based. Is there anything to be lost or to be gained by giving these patients some x-ray treatments along with these estrogenic tablet implants? I think there is. In my practice that is my method. I give these men courses of x-rays or courses of radium along with their estrogenic substances, and I feel that, at least to my finger these prostates don't grow as fast, are controlled and shrink up and do very well clinically. My longest survival on this situation is about three and one-half years. That man is apparently getting along about as well as a man 70 years old could. He has had that method of

treatment and no castration. He had a partial removal of the carcinoma surgically and has had since that time estrogens. He has had several courses of x-rays.

DR. HENRY SANGREI, Philadelphia: The adult prostate in its secretory stage has only two types of hormones—androgens and estrogens. Androgens in excess produce hyperplasia. Estrogen produces metaplasia. It causes a decrease in the size and a cessation of the tall columnar epithelial cells. In recent years the concept of the self-governing action of the cancer cells has become standardized. Many men consider that few or no outside influences control the growth of the cancer cell; that even when dependent on the catabolic effects of a starving host they will proliferate and develop. This general pattern does not hold true with respect to prostatic cancer in man, which is often dependent on androgen for its survival, androgen seriously disturbing the enzyme mosaic of the cancer cell.

DR. WILLIAM P. HERBST, Washington, D. C.: All of us are confused about this problem. The main reason for the confusion is the incidence of a large number of clinical courses which do not conform to what seem to be the basic principles. That, of course, is dependent on the fact that the human mechanism from a biochemical standpoint is most complex. Dr. Lespinasse brought up the question of the vitamins stimulating the malignant cells. From the small clinical experience that I have had it is my impression that even though the vitamins may stimulate the cancer cells the patient, as far as his sense of well-being, comfort and tongue are concerned, is definitely in a better situation. When we introduce into the body these various biochemical substances they do not necessarily have to remain as that biochemical entity, and, as a matter of fact, they do not, as proved by research. It is quite conceivable that estrogen may be transformed into androgen. I have had clinical cases which would suggest that as an explanation of the clinical course. We can administer large quantities of these substances, and urinary excretion tests do not run comparative to the amount injected. Dr. Lespinasse also mentioned the x-rays. Clinically, when estrogens are being administered and the patient is complaining of pain over the shoulder or over the back or over the hip, the roentgenologist is able to give comfort with a much smaller dose of x-rays than these patients have been accustomed to obtaining with radiation in like cases without the administration of the estrogen. The present status of acid phosphatase in the correlation of metastasis is one of those things that we can't understand. Clinically some of the patients with extensive metastases run courses completely comparable to the acid phosphatase levels; some of them do not. Some of the worst cases instead of having elevated phosphatase levels have levels down as low as two points. That is one of the confusing things and that is what put us all in this mental confusion Dr. Alcock has described. The potential period of control is going to depend on the performance of castration and the subsequent administration of these various substances when symptoms of malignant progress indicate them. The further off we can put the administration of the estrogens after the performance of castration, the longer is going to be life expectancy and comfort.

DR. J. A. C. COLSTON, Baltimore: It has been generally agreed that there is a certain percentage of cases, perhaps a small percentage, that is suitable for radical surgery. Endocrine therapy is palliative and gives marvelous results in certain cases. Before the endocrine treatment was introduced by Dr. Huggins, I had rather definite ideas on the question of carcinoma of the prostate in that the radical operation could be done in some cases and that for the advanced cases palliation should be carried out by operation or x-rays for the purpose of preservation for as long a time as possible of as nearly normal urinary function as possible. The studies of Dr. Huggins have not modified that view. Certainly all of the men who have discussed the situation have noted definite regression from diethylstilbestrol. Dr. Brice Vallett in the *Delaware State Medical Journal* described a case of advanced carcinoma of the prostate with a frozen pelvis, in which orchiectomy was done, followed by tremendous regression of the growth; he then did a radical

operation, not perhaps in the hope of a complete cure. In the majority of cases of such extensive malignant disease there would probably be a recurrence of the disease. But I think this patient will probably do far better with this method of management. Recurrence may take place, but I think his life will be extended and the future made more comfortable. In regard to diethylstilbestrol, since the first of the year we have carried out diethylstilbestrol treatment on 4 patients who had a rather extensive carcinoma of the prostate but no extension into the vesicles; the whole gland was involved by malignant disease but no metastases were demonstrable. In these 4 cases there was a very definite regression and in all of these cases radical operation has been done since this time without any particular difficulty. I believe that diethylstilbestrol treatment should be tried in cases which appear a little unfavorable for the radical operation in the hope that regression will occur to such a degree that this operation can be carried out. I believe, therefore, that with selected endocrine therapy more and more cases will be suitable for complete radical extirpation.

CORRELATION OF THE PURITY OF PENICILLIN SODIUM

WITH INTRAMUSCULAR IRRITATION IN MAN

ROBERT P. HERWICK, M.D., PH.D.

HENRY WELCH, PH.D.

LAWRENCE E. PUTNAM, M.D.

AND

ARMAND M. GAMBOA, M.D.

WASHINGTON, D. C.

It has been reported¹ by both the Army and the Navy that certain lots of commercial penicillin sodium produce severe pain on intramuscular injection. In some cases repeated injections have been followed by the formation of sterile abscesses containing insoluble material with no antibacterial activity. In general the lots of penicillin causing the most severe reactions were produced by only one or two manufacturers. Occasionally, however, other manufacturers' lots resulted in mild to moderate irritation on intramuscular injection.

At the request of the Army and the Navy the present study was undertaken to determine the factors causing pain following intramuscular injection of penicillin. Two hundred and thirty individuals, most of them with sulfonamide resistant gonorrhea, were treated with penicillin sodium obtained from seventeen manufacturing sources.

In preliminary studies on 100 patients an attempt was made to correlate pain in patients following intramuscular injection with the reactions obtained following intradermal injection of the same material in man and in rabbits. In man the intramuscular injections consisted of single doses of from 10,000 to 25,000 units of penicillin and the intradermal injections were made with 1,000 units in a volume of 0.05 cc. of salt solution. Rabbits were injected intradermally with 2,000, 4,000, 6,000, 8,000 and 10,000 units contained in 0.5 cc. of distilled water. Using either vesiculation in man or edema and hemorrhage in rabbits as an index of irritation, it became evident that it was not possible to correlate these reactions with pain produced on intramuscular injection in man. Certain commercial prepa-

1. Personal communications to the author.

rations produced vesiculation (primary irritation) on intradermal injection, while the same material on intramuscular injection gave variable pain responses. When 6,000 units or more of penicillin intradermally in rabbits produced definite edema and hemorrhage, such products would in most cases produce pain on intramuscular injection in man. Unfortunately, however, the converse of this did not follow; that is, when 6,000 units failed to cause edema and hemorrhage in the skin of rabbits, such preparations were not always painless on intramuscular injection.

In estimating pain in the next 100 patients several manufacturers' products of varying potencies were used and a control injection of 5 cc. of isotonic solution of sodium chloride was made in the corresponding area on the opposite side of the body. In this group of persons the injections of penicillin were made into the buttocks, triceps or deltoid. The drug was dissolved in isotonic solution of sodium chloride in a concentration of 5,000 units per cubic centimeter, and 5 cc. was given. Pain was reported as being either very slight, slight, moderate or pronounced and recorded as 1+, 2+, 3+ or 4+. If the pain radiated to the knee or elbow the valuation of the pain was raised one step, and if the pain persisted until the time of the next injection (three hours) it was also raised in value to the next higher grade; that is, a moderate pain which radiated down the extremity or which lasted three hours or longer was considered to be equivalent to a severe pain. One investigator was responsible for the interpretation of the degree of pain in all cases. The observations were made by the "blind test technic," i. e. the operator had no knowledge of the potency of the solution being tested.

The following results were obtained: Of 269 injections of saline solution 173 caused no pain, 56 caused 1+ pain, 34 caused 2+ pain, 6 caused 3+ pain and no injections caused 4+ pain. By contrast, of 269 injections of penicillin 51 caused no pain, 47 caused 1+ pain, 81 caused 2+ pain, 65 caused 3+ pain and 25 caused 4+ pain. From these data it was evident that penicillin produced more pain on intramuscular injection

manner that the data obtained could be subjected to statistical analysis.

Each of the 30 patients received 75,000 units (25,000 units per injection) of penicillin sodium dissolved in isotonic solution of sodium chloride in a concentration of 5,000 units per cubic centimeter. Injections were

* B = buttocks, T = triceps, D = deltoid.

† 0 = no pain, 1+ = very slight pain, 2+ = slight pain, 3+ = moderate pain, 4+ = severe pain.

Relationship of pain produced to site of injection and potency of penicillin sodium.

tion than isotonic solution of sodium chloride. In addition, it appeared that less pain resulted from injection into the buttocks than into the triceps or deltoid and that there was a correlation between the potency of penicillin and the pain produced. A statistical review of our data, however, could not be made. It was decided, therefore, to treat a group of 30 patients in such a

made into the buttocks, triceps and deltoid, and these were controlled by injections of saline solution contralaterally. The pain was estimated as described in the previous study, but in all cases in which the subject experienced pain following injection of saline solution the degree of pain was estimated and subtracted from the degree of pain produced by injection of penicillin and recorded as the difference. For example, pain estimated as 2+ from saline solution and 3+ from penicillin was recorded as 1+ pain. In a few cases the pain caused by injection of saline solution was equal to or greater than that produced by penicillin. In these cases the injection of penicillin was reported as having produced no pain.

The penicillin was of commercial manufacture and varied in potency from a low of 175 units per milligram to a high of 1,127 units per milligram. Six different concentration levels were used and, in choosing the material to pool, care was taken to obtain lots that were of approximately the same potency at all levels. The variation in potency of the samples of penicillin sodium and the number of manufacturers' products are shown in the accompanying table. Since there is some evidence that the depth of color of penicillin preparations is related to purity, the light transmission through a red filter of the pooled samples was determined at each concentration level. As the potency of the penicillin solu-

tions increased, the transmission of light through these solutions also increased.

For statistical analysis of the data a balanced incomplete block type of experimental design² was used. This type of design was so arranged that although each patient was injected with only three of the six potency levels each potency occurs with every other potency the same number of times. For instance, as shown in the table, sample *a* is given to the same patient as sample *b* in 6 instances (patients 1, 2, 11, 12, 21 and 22). This design was for 10 patients only. However, in order to determine whether the order in which the injections were made affected the pain response, two additional groups of 10 patients each were included. In the first 10 patients the order of injections was buttocks, triceps and deltoid. For the second series of 10 patients the order was triceps, deltoid and buttocks, and for the third series deltoid, buttocks and triceps. In this way each potency was administered to 5 patients at each site of injection (as shown in the table). Thus a balance is obtained and the individual patient's responses do not give undue weight to any one factor.

In the chart the pain responses resulting from all injections are presented. With an increase in potency in units per milligram of penicillin there is a corresponding decrease in the pain produced. Of the three sites of injection, those made in the buttocks produced the least amount of pain. As shown by analysis of variance³ two factors were statistically significant in this clinical experiment, namely the site of injection and the potency of the penicillin.

CONCLUSIONS

1. There is a significant correlation between the purity (potency) of commercial penicillin sodium and irritation following intramuscular injection. With an increase in potency in units per milligram there is a corresponding decrease in the pain produced.
2. Intramuscular injection of penicillin produces a greater incidence and intensity of pain than isotonic solution of sodium chloride.
3. There is a correlation between the potency of penicillin and its light transmission.
4. Of the three sites of injection (buttocks, triceps and deltoid) the least amount of pain results from injection into the buttocks.
5. There is no significant correlation between the irritation produced by intradermal injection of penicillin in man or rabbits and that produced by intramuscular injection of this material.

Cosmetic Dermatology.—Cosmetics was one of the earliest interests of civilized man, and when it comes to cosmetic dermatology the Ebers Papyrus gets into its full stride. The amount of space given to gray hair and baldness indicates not only that they are not afflictions peculiar to modern man but that there were the same frenzied and fruitless efforts to escape them that there are today. There were remedies to remove moles, to prevent or remove wrinkles, to make the face smooth, to improve its color, to beautify the skin. There is remedy after remedy to prevent or cure baldness and grayness and to dye the hair. There are even prescriptions for gray eyebrows.—Pusey, William Allen: *The History of Dermatology*, Springfield, Ill., Charles C Thomas, 1933.

THE ROLE OF INJUDICIOUS ENDOCRINE THERAPY

IN THE DELAYED DIAGNOSIS OF
UTERINE CANCER

LEWIS C. SCHEFFEY, Sc.D., M.D.

DAVID M. FARELL, M.D.

AND

GEORGE A. HAHN, M.D.

PHILADELPHIA

Our purpose in this presentation is to direct attention to a practice that is proving to be a serious factor in the delayed diagnosis of uterine cancer. We refer specifically to the indiscriminate use of endocrine therapy for the control of abnormal bleeding from the genital tract, when an organic cause for such hemorrhage has either been undiscovered or ignored. It is generally recognized, both by the profession at large and especially by workers in the field of pelvic malignancy, that delay in diagnosis is the most important explanation of the low curability rate of uterine cancer. Both patient and physician share in this responsibility.

Recognition that lack of knowledge, actual fear of learning the truth and associated reasons influence women to avoid medical consultation when abnormal vaginal bleeding occurs has led to intensive campaigns among the general public for cancer detection. The work of the Women's Field Army of the American Society for the Control of Cancer is an outstanding example of a sustained educational endeavor in cancer control, an effort that warrants the support and cooperation of all physicians. Any rational program that will influence women, not only to seek medical advice promptly when abnormalities appear, but to insist on an adequate pelvic examination as part of a routine, periodic check-up, should be furthered. Dr. Catharine Macfarlane and her group have shown today what can be done in this respect.

What of the physician's responsibility? Granted that in a very small minority of patients cancer of the uterus may exist without causing any untoward symptoms whatever, clinical experience and statistics prove that in the vast majority of instances abnormal bleeding from the genital tract is the commonest and most frequent symptom of the disease. Leukorrheal discharge, unless blood stained, is of much less significance, for vaginal discharge alone most often results from benign causes. Pelvic pain when associated with cancer unfortunately means a definite advance of the disease. Apart from this interpretation pelvic pain per se usually brings the patient to us for advice, and this provides an opportunity for careful examination, in the course of which a suspected or early lesion might be observed more promptly than would otherwise be the case.

Clinically, certain distinctions must be borne in mind with respect to the location of uterine cancer. Cervical cancer may occur at any time during the reproductive period, although the majority of patients afflicted are in the menopausal or postmenopausal epochs. Twenty-seven per cent of the patients observed in the Department of Gynecology of the Jefferson Medical College Hospital have been women under 40 years of age when first seen.¹ Friability of the tissue is characteristic of

From the Department of Gynecology, Jefferson Medical College Hospital.
Read before the Section on Obstetrics and Gynecology, at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

1. Scheffey, L. C.: Experiences in the Treatment of Carcinoma of the Cervix Uteri, *Radiology* 40: 436 (May) 1943.

malignant change, but biopsy is always indicated when abnormal bleeding is associated with pronounced hypertrophy, eversion and endocervicitis. Helpful diagnostic adjuncts comprise the use of the Hinselmann colposcope, the Schiller test and the stained vaginal smear method of Papanicolaou, more recently emphasized by Meigs and others. Biopsy, however, must be depended on finally for certainty of diagnosis.

On the other hand, fundal cancer is usually manifested primarily by postmenopausal bleeding. This has been true of 79 per cent of such patients seen at Jefferson. The remaining 21 per cent were over 40 years of age, however, and had not yet ceased menstruating when the diagnosis was made. Only 1 patient seen was under 40.² In this condition, curettage is essential to establish an accurate diagnosis and to determine proper treatment. Accompanying fibromyomas of the uterus tend to confuse the diagnosis of cancer in the premenopausal group, and this may result in inadequate treatment if preliminary curettage is omitted, either by performing incomplete surgery or by administering insufficient radiation therapy for a supposedly benign condition.

In support of the recognized prevalence of organic causes for abnormal uterine bleeding, one may also cite the findings of Mussey and Wilson.³ They reviewed the records of 200 patients who registered at the Mayo Clinic between July and September 1937 because of this symptom, finding 80 cases (40 per cent) of uterine fibromyomas and 27 cases (13 per cent) of cancer of the uterus.

Abnormal bleeding then, next to the ideal periodic pelvic examination, is the one incident that may enable the inquiring physician to confirm or disprove the presence of uterine cancer. This symptom, properly evaluated and managed, represents an ideal opportunity for prompt action; it is an opportunity that does not knock at the diagnostic door again. No diagnosis is easier to make, no treatment easier to initiate. The physician to whom the bleeding patient first comes for advice is the one on whom the primary responsibility rests for proper management.

It is unfortunately true that only too often the histories of uterine cancer patients show glaring errors of omission or commission in their primary management. Pelvic examination has often been omitted entirely or inadequately performed. Sometimes postponement has been suggested "until the bleeding stops." Patients have even been told not to worry—that the condition is one due merely to "change of life"—and that an examination can be made "later on." Of a score of patients coming into our clinic because of abnormal bleeding, the records show that 15 of them had received oral medication without examination, while 5 had been given either "electrical treatments" or cauterizations or simply told to use a vaginal douche. Biopsy, curettage or reference to a gynecologist or clinic was never even mentioned. Facts like these are not new; they are well known to the profession at large.

In recent years a new hazard has gradually become evident. The current popularity and ease of administration of glandular preparations has resulted in their indiscriminate and injudicious use in an attempt to

control abnormal uterine bleeding. Rapid advances have been made in the preparation and variety of potent endocrine products, both natural and synthetic in character. The use of such products should be based on a sound knowledge of their respective physiologic properties. Adherence to scientific principles, accompanied by honesty of purpose and fineness of judgment, is absolutely essential if good instead of harm is to result from their use.

In no sense do we wish to disparage the possible benefits of carefully controlled endocrine medication. It is quite permissible to attempt to manage the functional bleeding of adolescence and the early reproductive period with endocrine therapy, including thyroid, together with adequate general measures, provided a careful physical survey of these younger women, including pelvic examination, has eliminated organic disease and that logical consideration has likewise been given to the physiologic reasons for using this or that endocrine preparation. Even so, the possibility that such therapy may disturb the delicate endocrine balance of the individual should always be borne in mind.

When abnormal bleeding is present during the late reproductive, menopausal or postmenopausal periods, there is much less justification for prolonged and experimental endocrine therapy. Well recognized radiologic and surgical measures are available in such cases, not only for the relief of organic pelvic disease, but even for the correction of proved functional bleeding—measures that are surer and far less time consuming than prolonged and often indecisive endocrine therapy.

In too many instances, by ascribing abnormal bleeding to purely functional causes, and without thorough investigation or even pelvic examination, endocrine preparations of various sorts are increasingly being administered to "cure" disorders that are really organic. Robert T. Frank, dean of gynecologic endocrinologists, in a comprehensive review relating to advances in endocrine therapy, has commented particularly on errors of this sort.⁴ Tragically enough, cancer has frequently been found to be the real cause of the hemorrhage. When the cause has eventually been discovered to be due to a benign lesion, the situation may not yet be beyond effective control; with cancer at fault, the outlook is often hopeless because of such procrastination.

These observations are not peculiar to us. They have been noted by others, and warnings such as these are being sounded more and more frequently in gynecologic presentations. To support this thesis and to emphasize our personal experience in these instances we will report in brief abstract the histories of 7 such patients who were observed in the gynecologic service of the Jefferson Medical College Hospital Philadelphia:

CASE 1.—F. S., a quintipara aged 62, admitted April 19, 1940 because of profuse bloody vaginal discharge and itching of six months' duration, had had the menopause and cessation of periods twenty years before. Thyroidectomy had been done two years prior to admission. No pelvic examination had been made. Endocrine injections had been administered by the family physician for functional bleeding over a period of six months, when the patient sought hospital advice because of dissatisfaction with the management of her case. Examination revealed carcinoma of the cervix, group 3 (Schmitz). The histologic diagnosis was squamous cell carcinoma of the cervix, with a high grade of malignancy. External irradiation was done prior to local radium application. The patient recovered and has been living and well for four years without further symptoms.

4. Frank, R. T.: Advances in Endocrine Therapy, *Am. J. Obst. & Gynec.* 47: 561 (April) 1944.

CASE 2.—F. M., a sextipara aged 50, admitted June 21, 1940 because of vaginal bleeding of two years' duration, had been given endocrine injections by the family physician for six months prior to admission, without pelvic examination, in the belief that the symptom was "due to the menopause." Pelvic examination at this late date revealed an extensive cervical growth and the patient was sent to the hospital. Examination revealed carcinoma of the cervix, group 4 (Schmitz). The histologic diagnosis was squamous cell carcinoma of the cervix with intermediate grade of malignancy. External irradiation was done prior to local radium application. The patient died of carcinoma one year later.

CASE 3.—M. V., a secundipara aged 48, admitted Dec. 6, 1941 because of vaginal bleeding of six months' duration, had had the menopause and cessation of periods one year before, when she received a series of endocrine injections simply "for the menopause" and without internal examination. Six months prior to admission vaginal bleeding began to occur at irregular intervals. Without pelvic examination, endocrine injections were again administered, and slight bleeding was noted almost every day. Finally a profuse vaginal hemorrhage took place and soon afterward the patient was sent to the hospital. Examination disclosed carcinoma of the cervix, group 3 (Schmitz). The histologic diagnosis was squamous cell carcinoma of the cervix, with an intermediate grade of malignancy. External irradiation was administered prior to local radium application. The patient died of carcinoma two years later.

CASE 4.—L. M., a secundipara aged 65, admitted Jan. 31, 1942 because of continued vaginal bleeding following both radium therapy and external irradiation received in other hospitals for postmenopausal bleeding, the cause of which had never been diagnosed histologically, had had the menopause fifteen years before that. With the primary appearance of postmenopausal bleeding, two years prior to the radium application and x-ray therapy, and without pelvic examination, endocrine therapy had been administered over a considerable period of time. When the patient was finally admitted to Jefferson Hospital, the histologic diagnosis of well advanced adenocarcinoma of the fundus, with an intermediate grade of malignancy, was made. External irradiation was administered, followed by local radium application. The patient died of carcinoma one year later.

CASE 5.—A. S., a septipara aged 50, admitted July 22, 1942 because of continuous vaginal bleeding of seven months' duration with resultant profound anemia, had been regarded as a functional problem off and on for the previous ten years because of conspicuous obesity and intermittent periods of irregular uterine bleeding. During this time she had received numerous courses of endocrine injections as well as thyroid. Since a diagnostic curettage five years before had shown cystic hyperplasia, the patient continued to be regarded as a functional bleeder until the resultant hemorrhagic state necessitated hospitalization. Examination revealed an intact cervix, but the fundus was symmetrically enlarged. Diagnostic curettage and microscopic study revealed adenocarcinoma of the fundus of low grade malignancy, and 4,800 mg. hours of radium was administered following the curettage. Because of extreme obesity, operation subsequent to the radium application was contraindicated and a second radium application of 4,800 mg. hours was carried out again four months later. The second curettage revealed residual adenocarcinoma of the endometrium with advanced degenerative change, but there has been no further bleeding to date. Recovery ensued. The patient has been living and well for two years.

CASE 6.—M. L., a primipara aged 44, admitted July 3, 1943 because of irregular vaginal bleeding of three years' duration, had been given endocrine injections for "menopausal bleeding," without pelvic examination, for six months prior to admission by the family physician. Failing to improve, she was admitted to a hospital in her vicinity, where external irradiation was administered for carcinoma of the cervix, clinical group unrecorded. The patient was then referred to Jefferson Hospital for radium therapy. Examination revealed a lobulated but contracted vaginal vault with localized necrotic areas and

parametrial fixation, group 5 (Schmitz). The histologic diagnosis was squamous cell carcinoma of the cervix, of low grade malignancy. Radium was applied locally. The patient recovered and has been well for one year.

CASE 7.—P. J., a primipara aged 40, admitted March 14, 1944 because of profuse vaginal hemorrhage, had irregular vaginal bleeding for seven months. Without pelvic examination, a protracted course of endocrine injections was given by the family physician over a period of six months. When an exsanguinating hemorrhage finally occurred, the patient was seen in consultation with other physicians, finally examined and sent to the hospital. Examination revealed carcinoma of the cervix, group 3 (Schmitz). The histologic diagnosis was adenocarcinoma of the cervix. External irradiation was administered prior to local radium application. Recovery is undetermined at this date.

It has been substantiated by the foregoing case reports that ill advised endocrine therapy, without thorough clinical study, is an important factor in the delayed diagnosis of uterine cancer. That the same inattention to accurate diagnosis may result in the postponement of adequate measures for benign conditions is well illustrated by the following reports of 2 patients recently admitted to the gynecologic service of the Jefferson Medical College Hospital. Such instances are not infrequent, but more cases need not be reviewed to clarify this particular point.

CASE 8.—L. B., a tertipara aged 39, admitted Jan. 16, 1944 because of menorrhagia and metrorrhagia of nearly two years' duration, during which time she had been receiving endocrine injections from her physician for control of the bleeding without any preliminary or subsequent pelvic examination, finally became dissatisfied and consulted another physician, who immediately diagnosed fibromyomas of the uterus, together with papillary erosion of a lacerated, hypertrophied cervix. The patient was referred to the hospital and the diagnosis was confirmed. A complete abdominal hysterectomy was performed, with conservation of both adnexa. The histologic diagnosis was multiple fibromyomas, subserous and submucous; papillary erosion of the cervix; endometriosis interna. The patient recovered.

CASE 9.—M. G., a secundipara aged 48, admitted March 7, 1944 because of menorrhagia, metrorrhagia and pelvic discomfort of two months' duration, had been given endocrine injections of various types regularly during that time by a physician's office nurse in a distant city without complete pelvic examination. When she returned to her home the patient's family physician promptly examined her and detected fibromyomas of the uterus associated with endocervicitis, hypertrophy and cervical polypi, which diagnosis was confirmed on admission to the hospital. A complete abdominal hysterectomy with bilateral salpingo-oophorectomy and lysis of adhesions from a previous operation resulted in recovery. The histologic diagnosis was multiple fibromyomas, subserous, intramural and submucous, with hyaline change; cervical erosion; endometriosis interna; follicular cystosis of the left ovary.

Attention should also be called to the uterine bleeding that may result from excessive and continued dosage with estrogenic substances primarily prescribed to combat the vasomotor disturbances incident to cessation of periods and the menopause. This type of bleeding is bound to be confusing, for the question immediately arises as to whether this substitution therapy is entirely responsible for the postmenopausal bleeding as an estrogenic "withdrawal" phenomenon or whether it is due to organic pelvic disease, particularly fundal cancer. Only a diagnostic curettage can settle definitely the problem thus created. Furthermore, the possibility of a carcinogenic effect on the postmenopausal genitalia or breast, particularly where susceptibility or a familial history of cancer exists, and entirely apart from a preexisting cancer, must also be taken into consideration. For the same reason it would

seem inadvisable to administer endocrine therapy for the control of vasomotor symptoms occurring after the use of radium or x-rays for either benign or malignant pelvic conditions.

As a matter of fact, many women exhibit little or no disturbance during the menopausal epoch. Quite a number of those who do complain of disagreeable vasomotor symptoms may be made relatively comfortable by a rational explanation of the physiologic changes responsible for their annoyance, plus appropriate sedation and the reassurance of a negative pelvic examination. Too often, however, the menopausal patient is led to believe that courses of "injections" continued over a long period of time are essential to her health and happiness. She may even be told to expect disagreeable phenomena with the advent of the "change of life" and such suggestions may come, not only from her intimates, but from her medical adviser as well.

When, after thoughtful consideration, estrogenic therapy is believed to be essential for the control of distressing menopausal phenomena that do not yield to the measures mentioned, it should be administered in the lowest possible dosage. Furthermore, "rest periods" of a week or so should be prescribed between courses of therapy, as advocated by Hepp⁵ and others. Whenever so-called "withdrawal bleeding" occurs, its possible significance should be promptly appreciated.

CONCLUSIONS

1. Endocrine therapy, as shown clearly in this presentation, instituted to control abnormal uterine bleeding, without preliminary examination to exclude organic pelvic disease, has resulted in the delayed diagnosis of uterine cancer in far too many instances.

2. A similar conclusion pertains to the delayed diagnosis of benign pelvic conditions amenable to surgical or radiation therapy.

3. The profession at large should be reminded constantly of the possible dangers and diagnostic confusion that may result from ill advised and injudicious endocrine therapy employed for the control of gynecologic disorders. The importance of a comprehensive general and pelvic examination to exclude organic lesions before instituting such therapy cannot be stressed too often or too forcefully.

255 South Seventeenth Street.

ABSTRACT OF DISCUSSION

DR. EDWARD D. ALLEN, Chicago: This paper reemphasizes the frequent lack of early diagnosis of bleeding from the genital tract of women. An appraisal of many of the extensive studies dealing with the treatment of carcinoma will reveal that in spite of the intensive educational program of the public and the medical profession for the control of cancer there has been only a slight increase in the number of early carcinomas found over that of ten years ago. A tidal wave of endocrine therapy is sweeping the country just as the vitamins have done. I am expecting daily to hear a radio announcer say "Get estrogens at your neighborhood drug store, they are great for your hot flashes or any other ills peculiar to the female sex." A large number of women of all ages have had hormones prescribed for them, without a complete physical examination, for everything from skin diseases inward. I do not believe we shall progress in the control of cancer of the female genital tract until we teach patients to demand pelvic examinations as a part of their routine check-up and to insist that doctors include it regularly in their complete physical examinations. To do this adequately we must start back in the mother-daughter contacts. One month ago I

treated with radium an extensive carcinoma of the cervix in a maiden lady who had been given estrogen for one year for the menopause before she was asked by her doctor for permission to make a vaginal examination. Our department has tried to enforce a rule to the effect that no patient is to receive hormones without a previous adequate pelvic examination. Every one seems to feel that the treatment of the menopause is so simple now that it needs no special knowledge or training. We have impressed the profession and the public with the advantages of the treatment of the menopause without at the same time stressing its dangers and disadvantages. Thousands of women between the ages of 35 and 65 are receiving hormones for bleeding presumably due to the menopause. We have abetted the assumption that almost anything that happens to a woman between these ages may be attributed to the menopause and have often ourselves forgotten at times that the menopause signifies cessation of menstruation. The vast majority of patients similar to those that Dr. Scheffey has presented have been overlooked not by lack of diagnostic acumen on the doctor's part but by sheer inertia or hesitancy in making a pelvic examination.

DR. JOE VINCENT MEIGS, Boston: Nearly every patient one sees in the office with uterine bleeding near or at the menopause has at one time or another had "shots" or has taken "pink" pills. It is reasonable to expect that sometime a growth, perhaps a malignant growth, may result. Injudicious use of endocrine therapy is to be condemned. It is true that large doses of estrogen or synthetic estrogen will occasionally check abnormal bleeding. The renal problem is as to whether it is safe to use such powerful treatment before a diagnosis has been made and whether one can wait to watch the result of such treatment. The chances of stopping the bleeding in cancer patients is not great, but benign bleeding will almost certainly cease. The danger is the possibility of obscuring a malignant tumor, and lack of appreciation of such a possibility may be extremely serious. For these reasons estrogen or diethylstilbestrol should not be given to patients until the "bleeding" is thoroughly explained. In young people, in the attempt to stop ovulation as a diagnostic test, and for "hot flashes" or menopausal symptoms in the older age group, estrogen is of real value. In the older age group with bleeding, such treatment is fraught with danger and should not be used until a curettage has demonstrated the absence of cancer. An endometrial biopsy is not sufficient. This method of deciding whether or not cancer is present is not sound and may result in missed diagnoses; and a missed diagnosis may be fatal. I have had 2 patients who were given estrogen in the form of diethylstilbestrol who had uterine cancer, one of the endometrium and one of the cervix, and a great deal of time was lost before proper treatment could be instituted. The proper method of approach to vaginal bleeding is a complete study of blood disorders, vitamin deficiencies, sympathetic nervous system abnormalities, and in all patients over the age of 30 a diagnostic curettage with removal of as much endometrium as possible. Endometrial biopsy is not sufficient. Estrogen should be given only to those who have proved benign bleeding and to patients with definite menopausal symptoms without bleeding. Too many women are regarded as having menopausal symptoms from the age of 30 upward. Synthetic estrogen treatment is inexpensive and easy but, although it seems simple, should be considered as dangerous until proved otherwise.

DR. JAMES ALBERT CORSCADEN, New York: To the difficulties of diagnosis brought about by the injudicious use of estrogens should be added the possible etiologic factor which these substances may have. In the past year there have been several cases in which there was a close coincidence between the administration of large doses of estrogen and the carcinoma of the corpus which appeared a year or two later. In the cases of carcinoma of the uterus following many years after a radiotherapeutic menopause, uterine bleeding was the indication for treatment in all cases in the first instance, and there was a high incidence of cystic and glandular hyperplasia among those who subsequently developed carcinoma. These items suggest some relationship between estrogenic stimulation and the later development of carcinoma.

5. Hepp, J. A.: Menopausal Management: A Further Report on Diethylstilbestrol, *Pennsylvania M. J.* 47: 363 (Jan.) 1944.

Dr. KARL H. MARTZLOFF, Portland, Ore.: Since the monograph of Papanicolaou and Traut and more recently the article by Dr. Joe Meigs, reference to the stained vaginal smear test for detecting carcinoma of the cervix uteri is being made repeatedly. The test is not designed to take the place of tissue removed for biopsy from the cervix with either the curet, the scalpel or the endothermy unit. It is designed primarily as an exploratory test to detect cancer provisionally where it may otherwise not be suspected. In the event that the stained smears arouse the suspicion of cancer, this must be verified by microscopic study of tissue properly obtained and prepared for microsection. The test, in my estimation, has its limitations for these reasons: It requires one who knows how to stain these preparations. After the stained preparation is once prepared, the matter of interpretation arises. I do not believe that the average pathologist, unless he has been studying vaginal smears, is qualified to interpret a stained vaginal smear with the idea of making a reasonably correct presumptive diagnosis of cancer. Finally, the element of time is not inconsequential if these preparations are to be carefully scrutinized by one who is not in more or less constant practice with this technic. The foregoing considerations are mentioned so that a technic as valuable as this may prove to be will not cause disappointment merely because its purpose and field of usefulness are not appreciated.

Dr. RICHARD W. TELINDE, Baltimore: Dr. Karnaky is one of the greatest advocates of diethylstilbestrol therapy. He has made a great many statements in the literature with which many of us do not agree. For instance, he said that bleeding fibroids can practically always be satisfactorily treated with diethylstilbestrol. He states that it is just a matter of getting the proper level of diethylstilbestrol. I think this is the place to thresh these things out.

Dr. KARL JOHN KARNAKY, Houston, Texas: When I first discovered that diethylstilbestrol would stop uterine bleeding I did not think that some doctors would use diethylstilbestrol to stop uterine bleeding and not take a biopsy of the endometrium or even do a pelvic examination. I fully agree with Dr. Scheffey on this matter. Diethylstilbestrol in sufficient doses will stop uterine bleeding in a few hours. Previously there was nothing that could be taken by mouth that would stop dysfunctional uterine bleeding quickly. In such cases my associates and I give five 5 mg. to twenty 5 mg. tablets (25 to 100 mg.) now and 10 to 25 mg. every fifteen minutes until the bleeding stops and then 5 to 10 mg. every night for thirty to sixty nights by mouth. We have done thousands of laboratory tests on over 3,000 patients receiving diethylstilbestrol. In all the tests we have been unable to find any damage from diethylstilbestrol. Our latest work on uterine bleeding and diethylstilbestrol may be found in the December 1943 issue of the *Journal of Clinical Endocrinology*. In this paper I reported over 500 cases of dysfunctional uterine bleeding treated with diethylstilbestrol. I have devised a series of charts based on the theory that at a certain estrogenic level the woman menstruates or bleeds. Above this level, as during pregnancy and between menstrual flows, she is amenorrheic. During menstruation or uterine bleeding her estrogenic blood level is in the estrogenic bleeding level. Below this estrogenic level, as before puberty and after the menopause, she is amenorrheic. This is the basis for the use of diethylstilbestrol for uterine bleeding. By giving diethylstilbestrol one raises the estrogenic blood level out of the estrogenic bleeding level, and so the bleeding stops and the ovaries undergo temporary atrophy. I wish to emphasize the statement of the Council on Pharmacy and Chemistry of the American Medical Association that "estrogens are to be used to control the uterine bleeding until the cause can be found."

Dr. U. J. SALMON, New York: To the list of instances in which injudicious endocrine therapy has been instrumental in delaying the diagnosis of uterine cancer, already discussed, I should like to add the danger of assuming that uterine bleeding which occurs during the course of estrogen therapy administered for the relief of menopausal symptoms is attributable to the estrogens alone, thus possibly overlooking a uterine cancer, and the danger of treating abnormal uterine bleeding with androgens without a preliminary diagnostic curettage. I have attempted to avert both these dangers by performing an endometrial biopsy in every case of bleeding which occurs during the course of

estrogen therapy, followed by a diagnostic curettage if the bleeding persisted, and also by performing an endometrial biopsy or curettage in every case of menorrhagia and metrorrhagia before instituting any form of endocrine therapy. In 1 instance, in this manner, an unsuspected corpus carcinoma was discovered in a patient who had developed bleeding following diethylstilbestrol therapy. Both the estrogens and the androgens are valuable therapeutic agents for properly selected cases. It is regrettable that their injudicious use has led to some tragic mistakes. However, we should not condemn endocrine therapy because of mistakes committed by the misguided or inexperienced. By drawing attention to these mistakes and to the methods of averting them the authors have rendered an invaluable service to both the profession and the public.

Dr. LEWIS C. SCHEFFEY, Philadelphia: I am grateful to those of the section who have discussed this paper. The point we wanted to make is that, unless every doctor refuses to give endocrine therapy for abnormal uterine bleeding until examination has excluded organic pelvic disease, he has not done his duty, first to the patient, and second to the science and practice of medicine.

THE CONCENTRATION OF PENICILLIN IN VARIOUS BODY FLUIDS DURING PENICILLIN THERAPY

JEAN V. COOKE, M.D.

AND

DAVID GOLDRING, M.D.

ST. LOUIS

The absorption and distribution of penicillin in the various body fluids after parenteral injection and the duration of its survival in body fluids or cavities under normal and pathologic conditions are questions of considerable interest in penicillin therapy. Although some studies have been made in certain cases, there has apparently been no method for penicillin titer of such body fluids easily applicable to routine observations in clinical cases. In this paper we report the results of observations made on penicillin levels in the blood serum and other body fluids by the use of a relatively simple method which has yielded apparently consistent results and some useful information. The patients studied were for the most part infants and children in the St. Louis Children's Hospital who were receiving penicillin therapy and in addition a few adults from the medical service of Barnes Hospital on whom observations were made through the kindness of Dr. W. Barry Wood Jr. and his assistants.

The method of testing the titer of penicillin in the body fluids has been described in a separate paper¹ and consists in determining the smallest amount of the fluid which will produce complete inhibition of a standard strain (209) of *Staphylococcus aureus*. Such complete inhibition of this strain occurs regularly with 0.02 unit of standard penicillin when 0.1 cc. of a penicillin solution is used in the test so that 0.02 unit in 0.1 cc. or 0.2 unit per cubic centimeter is the lowest penicillin titer easily recognized by the method. In occasional instances we have used 0.2 cc. of fluid in the test, so that 0.1 unit per cubic centimeter could be detected. Since our chief interest lay in the detection of conditions favoring the production of higher penicillin levels and gross rather than minor variations in penicillin concentration during therapy, the titer levels routinely were in relatively wide steps.

From the Department of Pediatrics, Washington University School of Medicine, and the St. Louis Children's Hospital.
1. Cooke, J. V.: A Simple Clinical Method for the Assay of Penicillin in Body Fluids and for the Testing of Penicillin Sensitivity of Bacteria, J. A. M. A., to be published.

Usually 0.1 cc. of undiluted fluid, of 1 in 2, 1 in 5 and 1 in 10 dilutions were used, corresponding to 0.1, 0.05, 0.02 and 0.01 cc. respectively, and the lowest dilution giving complete inhibition was called the titer or level and expressed in units per cubic centimeter as 0.2, 0.4, 1 and 2 units. It is apparent that these titers actually indicate minimum levels, since, for example, 0.4 is more than 0.4 but less than 1 unit per cubic centimeter. In some cases additional dilutions giving more exact levels were done, but in general it was felt that except in special instances the information obtained by determining the titer within 0.1 or 0.2 unit per cubic centimeter at the higher levels would not justify the additional technical work involved.

A few general statements may be made regarding the material and the results.

It is apparent that one of the most important factors in the penicillin level is the time that has elapsed since the penicillin was injected, and it is therefore important to supplement any figures by supplying this elapsed time. Consequently we will speak of "one hour" or "two hour" blood (serum) levels to indicate that penicillin was injected one or two hours before the specimen was taken and twenty-four hour spinal fluid levels when the specimen was taken twenty-four hours after an intrathecal injection. In this connection it may be mentioned that in the routine administration of penicillin at stated intervals by nurses in a busy service and with reduced wartime personnel there may at times be some irregularity in the time the dose was given. We have felt that an occasional discrepancy in the blood penicillin level might be related to some such irregularity, but the general results have been so consistent that this has apparently played a minor role. An interesting example might be cited in which we were much disturbed to find a three hour blood level higher than the two hour blood level, but on investigation it was learned that the patient by mistake had been given a dose of penicillin at the end of two hours.

The potency of the penicillin used in therapy has not been tested routinely, but we have tested the commercial products at times and in 10 instances have found that the titer was identical with a standard penicillin while occasionally it was higher. Only once was a product tested and found defective. At one time, soon after penicillin was made available, some of our routine blood level tests showed only traces of penicillin. An examination of the particular preparation used on these children gave a titer of only about one-fourth its rated potency. With this single exception we have no observations which would indicate that the penicillin used was not of standard strength.

The unit dosage of penicillin used in infants and children is much higher as compared with the body weight than in adults and gives an opportunity to observe the effect of such relatively larger doses. For this reason we have included the body weight and sometimes the approximate units per kilogram dosage. In general, however, no proportional relationship was noted attributable directly to the units per kilogram dosage.

The results to be presented are taken from about 1,000 penicillin determinations of various body fluids over a period of months on more than 40 patients, most of them infants and children. Many of the tests were done as routine blood levels on patients receiving penicillin for various acute infections and were duplications which served only to confirm the reliability of the method. Although certain of the observations were

made from deliberately planned experiments of penicillin injections, in most instances the tests were adapted to the routine clinical penicillin therapy. For this reason there were certain omissions of observations which might have been of interest.

For the purpose of presentation and discussion, we have divided the observations into several groups dealing with the penicillin concentrations found in various fluids under different conditions. Certain of these are sufficiently similar to allow them to be tabulated, but in other categories the conditions in different patients varied so much that it is necessary to describe briefly some of the individual cases. No attempt will be made to discuss the clinical effect of penicillin therapy in the patients, but in most of them it was quite satisfactory in curing the infection.

BLOOD CONCENTRATION CURVE OF PENICILLIN AFTER ADMINISTRATION BY VARIOUS ROUTES

The usual method of injecting penicillin is intramuscularly, and we have followed the blood levels at intervals on a number of patients after varying doses by this route. In table 1 are collected 23 separate blood curves on 14 patients, in some of whom the levels after intramuscular injection are compared with those after subcutaneous administration while others received only intramuscular or subcutaneous penicillin. In 1 case the levels after an intravenous dose were compared with those found after intramuscular and subcutaneous injection. Most of these patients had been receiving penicillin regularly for a period of days in doses of from 300 to 2,800 units per kilogram of body weight when the observations were made, although 2 were given only a single large dose.

In general, the results are consistent in showing that both with intramuscular and with subcutaneous injections of penicillin the highest blood level occurs within thirty minutes and by one hour it has fallen almost 50 per cent, while in the second hour the drop is still more striking. In the tests made ten minutes after the injections also no striking differences were noted between the intramuscular and subcutaneous routes, and it was rather surprising that such rapid absorption took place as indicated by titers of more than 0.5 unit per cubic centimeter. In the single patient (Louise F., table 1) in whom the penicillin blood levels were followed after an intravenous injection, the highest level (2 units per cubic centimeter) was found at ten minutes, as was to be expected. It was of interest, however, that the half hour and one hour levels were essentially the same as those after intramuscular and subcutaneous injection of the same dose of penicillin in this patient. We have had no opportunity to follow the blood penicillin levels after continuous intravenous or continuous subcutaneous administration.

The subcutaneous injection of penicillin therapeutically has not been recommended because of the belief that by this route absorption was slower and more irregular than after intramuscular injection and that such injections were more painful. The observations recorded in table 1 show no evidence of any difference in absorption between the two methods if one can judge by the blood levels attained. In our experience the subcutaneous injections have produced only a slight burning sensation lasting a short time and have not caused more discomfort than intramuscular injections. Indeed, several adults on whom both kinds of injection were used stated that the subcutaneous was less annoying. The 2 children Janet C. and Charles H. (table 1)

who received single doses of 25,000 and 100,000 units respectively by the subcutaneous route made little objection to the procedure. The penicillin blood levels in these 2 subjects varied somewhat from the other patients who had been receiving regular injections. In 1 (Janet C.), who was given 25,000 units, the half hour and one hour levels were identical (0.8 unit per cubic centimeter) while in the second (Charles H.), who got 100,000 units, the one hour level (4 units per cubic centimeter) was ten times that found at one-half hour and at one hour (0.4 unit per cubic centimeter). We have no explanation to offer for these differences except the possibility that single large doses may react differently from continued regular injections. Some observations which suggest that the levels tend to be higher after repeated injections will be mentioned later.

One discrepancy appears in 3 patients (Robert H., Iola B. and Dr. V.) listed in table 1, in whom very much lower blood levels were attained than expected from the dosage of penicillin given and when compared with all the other patients studied. All 3 had

meter or less, but in most of the children receiving penicillin regularly every three hours and followed for a number of days the blood level at two and one-half to three hours after a penicillin injection has often been from 0.2 to 0.4 unit per cubic centimeter and occasionally has been as high as 1 unit. This is illustrated in table 2, in which most of the patients were older children and also in table 4, in which only infants are included. The units of penicillin per kilogram of body weight given intramuscularly is indicated, but this appears to bear no relation to the three hour level in the blood.

The final disappearance of penicillin from the blood at least to the point where it can no longer be recognized by the method used is of some interest, although it seems doubtful if such small amounts could be of therapeutic value. In only 3 children have we made tests at intervals of two or three hours after the discontinuance of intramuscular therapy. In 1 0.1 unit per cubic centimeter (the lowest titer possible by the method used) was found at four hours but not at six

* Single dose.

received penicillin regularly for some time with relatively little clinical effect. One (Robert H.), who had received 500,000 units in an experimental study, had generalized sarcomatosis, so that no clinical change could be expected. The 2 others, however, had localized infections which showed little change during the therapy. One possibility that suggested itself for the low levels observed was that the penicillin preparation they were receiving at the time the tests were done was below standard. This seems much less likely, however, than the possibility that some individuals do not attain the usual blood levels from causes not yet understood. These observations suggest that especially in patients who are not showing the desired clinical response to penicillin therapy it would be of some value to determine by testing whether penicillin was present in the blood at the expected level.

The disappearance of penicillin from the blood seems to be much more irregular than the initial rise in blood levels after injection. In table 1 it will be noted that the two hour blood penicillin level in most of the cases shown has a tendency to be around 0.2 unit per cubic centimeter. Tests done on other patients after two hours show considerable variation. In some we have found the three hour level to be 0.1 unit per cubic centi-

hours, in another 0.1 unit was found at six hours but not at nine hours, while in the third 0.1 unit was found at eight hours although no later tests were done. These observations indicate that in the occasional case penicillin may be recognized for as long as eight hours after the last intramuscular injection.

THE EXCRETION OF PENICILLIN FROM THE BLOOD INTO THE SPINAL FLUID

Previous observations have indicated that penicillin does not pass readily into the spinal fluid from the blood stream in adults. Our observations have been made in infants from 4 to 34 months of age who received relatively much larger doses of penicillin (500 to 5,000 units per kilogram of body weight) than usually given to adults. The results are given in table 3, in which observations on 9 patients are shown. All were given penicillin intramuscularly except 1, who received an intraperitoneal injection. In 4 of the 9 cases 0.1 to 0.4 unit of penicillin per cubic centimeter was found in the spinal fluid from fifteen minutes to one hour after the intramuscular injection. All of these had acute meningitis. In the infant given penicillin intraperitoneally 0.2 unit per cubic centimeter was found four hours after the injection.

These observations indicate that when relatively large doses of penicillin are given intramuscularly it may be found in the spinal fluid within fifteen minutes to one hour but tends to disappear after one and one-half hours. It may be that penicillin is reabsorbed from the spinal fluid. In a single observation penicillin was present in the spinal fluid four hours after a large intraperitoneal injection.

There is a pronounced discrepancy between the small amount of penicillin found in the spinal fluid after intramuscular injections and the much higher titer in the pleural, peritoneal and subcutaneous tissue fluids to be mentioned later. This is apparently due to the fact that penicillin must be secreted into the spinal fluid probably through the choroid plexus and is not a simple osmotic diffusion from the blood, as occurs in the other fixed body fluids.

PENICILLIN LEVELS IN THE SPINAL FLUID AFTER INTRATHECAL INJECTION

In a small group of 7 infants with acute meningitis we have made daily observations on the penicillin level of the spinal fluid approximately twenty-four hours after intrathecal injection. All were receiving 10,000 units of penicillin once daily intraspinally, and most of the time 10,000 units was also given intramuscularly

* Every 4 hours only.

every three hours. The results of these observations have been collected and summarized in table 4. It will be noted that the twenty-four hour penicillin level in the spinal fluid tends to remain relatively constant in the same child during the period of therapy. This level is higher and may reach 1 to 2 units per cubic centimeter in the smaller babies who got relatively larger doses intrathecally and lower (0.2 to 0.4 unit per cubic centimeter) in older infants.

The possible influence of continued intramuscular injections on maintaining a higher spinal fluid penicillin level during intrathecal treatment has been considered, but we have no definite observations which tend to confirm this. In 2 of the patients (Jean LaR. and John M.) shown in table 4 the intramuscular penicillin injections were discontinued for a period of a week or more during the period of therapy without producing any decrease in the titer of penicillin in the spinal fluid.

Concerning the persistence of penicillin in the spinal fluid after stopping the intrathecal injections, observations were made on only 2 patients in table 4. One was a younger infant with high spinal fluid penicillin levels who continued to receive penicillin intramuscularly after discontinuance of the intrathecal treatment, which may have had some influence on the persistence of penicillin in the spinal fluid. This child (Virginia S.) had a twenty-four hour level of 2 units,

while the forty-eight hour and seventy-two hour levels were 0.4 unit, and at ninety-six hours the titer was less than 0.2 unit per cubic centimeter. The other patient (John M.), an older infant with a penicillin level of 0.1 to 0.4 unit per cubic centimeter in the spinal fluid, had had the intramuscular therapy discontinued

three days before the intrathecal penicillin was stopped without reduction in the spinal fluid penicillin titer. In twenty-four hours after the intrathecal penicillin was discontinued the spinal fluid level was 0.2 unit per cubic centimeter, but in forty-eight hours there was less than 0.1 unit. The only conclusion drawn from these observations was that penicillin may persist in the spinal fluid for as long as seventy-two hours after intrathecal injections have been discontinued.

A few observations have suggested that in both the blood and the spinal fluid the levels of penicillin may

TABLE 4.—Blood and Spinal Fluid Penicillin Levels in Infants with Acute Meningitis Receiving 10,000 Units Every Three Hours Intramuscularly and Once Daily Intrathecally

* Intrathecal dosage 20,000 units.

† Intramuscular dosage 5,000 units.

be slightly higher after several days of administration than following the initial doses. This possibility is suggested by the following cases, but we have not had the opportunity to confirm it further:

Ruth W., aged 12 years, with Rocky Mountain spotted fever, was given 10,000 units of penicillin intramuscularly every two hours. After the first injection the blood level at the end of

five minutes after the injection and the other in from 135 to 195 minutes. On the other hand, Rosenberg and Sylvester³ have found penicillin present in the spinal fluid in each of 8 adults, 6 of them after intravenous and the other two after intramuscular injections of 24 to 40,000 units of penicillin. The levels reported varied from 0.03 to 0.35 unit per cubic centimeter without a definite relation of the titer to the time of spinal fluid examination. Our results have indicated that penicillin is secreted into spinal fluid early after an intramuscular injection and at the time the blood penicillin level is at its height but at a titer considerably below that of the blood. This is in striking contrast with the diffusion of penicillin from the blood into the subcutaneous, pleural and peritoneal fluids, which tends to approximate the blood titer. Even though penicillin may be secreted into the spinal fluid during parenteral therapy, its concentration is relatively low and its presence apparently transient as compared with intrathecally injected penicillin. For this reason it would seem that as a means of practical therapy for acute meningeal infections the intrathecal route is far superior, since (1) the spinal fluid penicillin titer persists in good titer for twenty-four hours, (2) large doses are not toxic and (3) penicillin passes readily from the lumbar region up to the cerebral meninges. In the 2 instances in which we have made observations, the spinal fluid penicillin level during intrathecal therapy was not increased by continued intramuscular injections.

The penicillin curves in the blood after intramuscular injections of relatively large doses in infants and children have been somewhat higher than those reported by Rammelkamp and Keefer² in adults. It appears likely that this discrepancy may be due to the difference in methods used for assay. Whatever may be the true values, our results are consistent in showing the highest level of blood penicillin within an hour after repeated intramuscular and subcutaneous injections, with the curve showing a higher peak at the end of thirty minutes and falling off rapidly during the second hour. When penicillin is injected every three or four hours, the concentration in the blood undergoes rather wide variations and only intermittently reaches a presumably effective level. Often, although not always, by the end of the third hour the titer is too low to be considered effective even against very sensitive bacteria. It has been shown¹ by *in vitro* tests that there is a rather wide variation in sensitivity to penicillin even of relatively sensitive organisms, since various strains of *Staphylococcus aureus* and of meningococci differed considerably in susceptibility to penicillin. The statement that *Staphylococcus aureus* or the meningococcus is sensitive to a certain concentration of penicillin therefore apparently applies only to a certain strain of the organism and not to all strains. It is possible that this factor is concerned in certain cases of *Staphylococcus aureus* infection in which penicillin therapy has been ineffective.

Because of the variations that occur in penicillin saturation of the blood and body fluids with different dosages, routes and intervals of injection, it is apparent that, when a patient is said to be resistant to penicillin therapy, not only is the penicillin sensitivity of the infecting organism of importance but also the titer of penicillin in the body reached by the method of ther-

apy employed. It is evident from our observations (table 1), for example, that 10,000 units given at hourly intervals maintains a considerably higher level than 20,000 units every two hours. This raises the question whether in such cases attempts to maintain a continued higher blood penicillin level by more frequent injections would have an advantage over a fluctuating blood penicillin curve with only recurring high peaks obtained by injections at longer intervals. Our opportunity to secure clinical evidence to support the possible advantage of such more intensive therapy in penicillin resistant infections has been limited, but we have recently treated a patient with subacute bacterial endocarditis due to a resistant organism who showed progressive clinical improvement with increasing the intensity of therapy:

Judith H., aged 5 years, with congenital heart defect, had had fever for a period of two months. In the first week after admission she appeared ill and toxic; the temperature ranged from 39 to 40 C. (102.2 to 104 F.) and four successive daily blood cultures showed *Streptococcus viridans*. She was then given 10,000 units of penicillin every three hours intramuscularly for five days. During this time there was but little improvement in the patient's clinical condition, and the temperature developed an irregular septic type with wide swings from 37 to 40 C. (98.6 to 104 F.). The penicillin dose was then increased, so that 10,000 units was given every two hours for the next ten days. There was a prompt fall in temperature for the first three days of this regimen to between 38 and 39 C. (100.4 to 102.2 F.), but for the following week the fever again rose at times to 40 C. (104 F.). The clinical appearance and actions of the child showed some improvement during this period, and two blood cultures remained sterile. The green streptococcus originally isolated from the blood had in the meantime been tested for penicillin sensitivity by the method previously described¹ and found to require 0.4 unit for complete inhibition. This would correspond to 4 units per cubic centimeter. Because of this high degree of resistance the penicillin therapy was increased to 10,000 units every hour for a period of seven days. During this week of intensive therapy the rectal temperature ranged from 36.6 to 38.2 C. (97.8 to 100.7 F.), most of the time below 37.5 C. (99.5 F.) and the clinical improvement was striking, the patient being alert, cheerful and with much improved appetite. Unfortunately, no comparative studies of the concentration of penicillin in the blood were possible during these periods of therapy, but the clinical improvement with more intensive treatment was striking and unmistakable. Because no more penicillin was available after she had been given three and a half million units, and since the patient's clinical condition appeared so good, she was allowed to return home on a "maintenance dose" (0.5 Gm. every eight hours) of sulfamerazine. Within two days after discontinuance of the penicillin therapy the fever rose to 40 C. (104 F.) and the previous toxic symptoms returned.

This case is cited as an infection clinically resistant to penicillin therapy due to an organism proved to be penicillin resistant, in which intensive penicillin treatment was required to produce clinical improvement. It appears that the maximum effect obtained by penicillin in this case was an inhibitory or bacteriostatic effect during the time of relatively high blood penicillin levels, and that when this effect was removed by discontinuing the injections the streptococci were again able to multiply unhindered.

The impression is gained from certain articles on penicillin therapy that the ideal method of intensive treatment and of maintaining a high blood penicillin level is by continuous intravenous drip. We have no observations on blood levels obtainable by this method at-

3. Rosenberg, D. H., and Sylvester, J. C.: The Excretion of Penicillin in the Spinal Fluid in Meningitis, *Science* 100:132 (Aug. 11) 1944.

compared with intramuscular or subcutaneous injections at hourly intervals, although we have shown that by the latter method relatively high blood levels can be maintained. As far as children are concerned, the use of continuous intravenous therapy except for short periods is accompanied by certain technical disadvantages which tend to limit its usefulness. In addition to the difficulty of maintaining a continuous flow, after twelve to twenty-four hours there is an added danger of thrombosis or of local infection which increases with the duration of the injection. Many who have had experience with the method would prefer other routes of therapy if equally effective and, as has been our practice in recent years, to reserve continuous intravenous injection for emergencies in which absorption from other routes is poor. We believe that the intramuscular or subcutaneous injection of penicillin at hourly intervals will maintain a high level in the blood and body fluids when this seems desirable and that, at least in children, this method is preferable to continuous intravenous injection.

SUMMARY

A study of the penicillin titer of the blood serum and other body fluids chiefly in infants and children during penicillin therapy showed the following:

After intramuscular injections, the concentration in the blood reached its highest level within thirty minutes, was still moderately high at one hour and fell rapidly during the second hour but often persisted at lower titer for three to four hours. In 1 instance it was found as long as eight hours after an injection.

The blood curves found after subcutaneous injection were quite similar to those after intramuscular injection, and even 100,000 units injected subcutaneously produced little discomfort.

Penicillin was found in the spinal fluid after intramuscular and after intraperitoneal injection but in much lower titer than that of the blood.

Penicillin injected intrathecally during acute meningitis persisted at high levels for twenty-four hours, when large doses were given and continued in 1 case for as long as seventy-two hours after intrathecal injections were discontinued. When relatively smaller doses were injected intrathecally the twenty-four hour level was lower, and no penicillin was found in forty-eight hours.

There was some evidence that penicillin injected intrathecally passed readily from the spinal to the cerebral meninges but less readily from the cerebral to the spinal meninges.

The concentration of penicillin in the subcutaneous tissues and in the pleural and peritoneal fluids tended to approximate that of the blood serum.

The titer of penicillin in the blood and spinal fluid was found to be much higher during renal insufficiency than in the same patient when renal function was apparently normal.

No close relationship was found between the units of penicillin per kilogram of body weight given and the concentration reached in the blood, although the highest levels were found in those receiving relatively large doses. In the same patient and with the same dosage the blood levels tended to remain constant, but considerable variation was found in the levels attained in different patients with similar dosage. There was some evidence that the blood concentration rose to a higher level after repeated injections at two to three hour intervals than after a single dose.

Continued intramuscular or subcutaneous injections of penicillin at intervals of one hour will produce a persistent high penicillin level in the blood and tissue fluids, and at least in children this method has certain advantages over continuous intravenous therapy in cases clinically resistant to penicillin.

Clinical Notes, Suggestions and New Instruments

A NEW MAGNET FOR FOREIGN BODIES IN THE FOOD AND AIR PASSAGES

MURDOCK EQUEN, M.D., ATLANTA, GA.

One of the most difficult and disturbing problems of endoscopy has been the removal of foreign bodies from the stomach. Even the use of the gastroscope and the flexible forceps under biplane fluoroscopic guidance does not circumvent such difficulties. The constant shifting of the position of the foreign body, in a space as large as the stomach, makes it difficult to establish contact between the forceps and the object.

Fig. 1.—The stomach is inflated with air by compression of the rubber bulb attached to the diaphragm and catheter. This inflation lifts away any collapsed portion of the stomach from the pin, allowing the magnet to be passed about freely, and the foreign body is unimpeded in being attracted by the magnet.

Herewith is presented the description of a magnet¹ of cast alnico which has proved highly gratifying in cases of magnetizable foreign bodies in the stomach and tracheobronchial tree. As shown in figure 1, the magnet is 3.5 cm. in length and 0.5 cm. in diameter and is attached to a Levine tube, size 12 E, through which a metal stylet has been inserted to increase the mobility of the tube. The other end of the Levine tube is attached to a rubber bulb, diaphragm and catheter, this apparatus being used for inflating the stomach.

From Ponce de Leon Eye and Ear Infirmary.
1. Manufactured by the General Electric Company.

The magnet is composed of alnico, an alloy of aluminum, nickel, cobalt and iron. Alnico is available in two forms, cast and sintered, and the cast type was employed in this magnet. Alnico is manufactured by pressing together a mixture of powders of the constituent metals under very high pressure in a mold and heating for a considerable time at a temperature near to the melting point in a carefully purified reducing-gas atmosphere.

Because of inherent mechanical properties, alnico magnets are brittle and cannot be reformed to different shapes. They require a considerably stronger magnetizing force to magnetize them completely than do other types of permanent magnet alloys. Alnico has more available external energy for a given volume than has any other permanent magnet material known at the present time.

The following case report is typical of the entire series of cases of foreign bodies removed by the magnet:

H. D., a girl aged 19 months, had swallowed her mother's hairpin (type known as bobby pin) twelve hours previous to

Fig. 2.—Bobby pin in stomach. Note the size of the pin in comparison to the size of the stomach.

admission. The history otherwise was negative. Physical examination showed that the child was moderately well nourished and was not acutely ill. The roentgenogram (fig. 2) shows the enormous size of the pin as compared with the size of the child's stomach.

Under fluoroscopic visualization the magnet was passed down the esophagus and introduced into the stomach. The stomach was then inflated with air by compression of a rubber bulb attached to a diaphragm, which in turn denoted the size of the inflated stomach. This inflation lifted away any collapsed portion of the stomach from the pin and permitted the magnet to be passed around in the stomach with ease. The pin quickly came into the magnetic field, was attracted to the magnet and was removed. The entire procedure lasted only eight minutes.

The new alloy magnet, alnico, is being proved of great value to medicine. For the past two years it has been available as a small permanent type eye magnet. Only a minority of foreign bodies of the food and air passages are magnetizable, but among those which are the use of this instrument will render unnecessary many abdominal operations and decrease bronchial instrumentation.

144 Ponce de Leon Avenue N.E.

COMPLICATIONS FOLLOWING A RAPID TREATMENT OF SCABIES

DEWITT C. DAUGHTRY, M.D.

Passed Assistant Surgeon (R), United States Public Health Service
DULUTH, MINN.

Over the years a great number of preparations have been recommended and widely used in the treatment of scabies, not one of which has proved entirely satisfactory. Until comparatively recently preparations containing sulfur have probably been more universally used than others. Owing to the lengthy treatment necessary and the high percentage of untoward skin reactions, sulfur preparations are being rapidly replaced by benzyl benzoate.

A review of the literature discloses that more uniformly satisfactory results have been credited to the use of benzyl benzoate preparations than to any other sarcopticide heretofore used. It is reported that Nielson¹ of Copenhagen began using 25 per cent benzyl benzoate in the treatment of scabies in 1912. However, not until its reintroduction by Kissmeyer² did it receive much public acclaim. Soon after his original paper, benzyl benzoate became widely used in Great Britain,³ but not until quite recently has it received due mention in this country.⁴ In recent months it has gained its deserved place as an effective sarcopticide in the United States.

The value of benzyl benzoate in the treatment of scabies is without question, but previous writers have presented it as a preparation to be used indiscriminately without fear of untoward reactions. To the contrary, I have made observations which have not previously been observed, or at least I was unable to find any reports. Those observations warrant the writing of this report.

Thousands of cases of scabies treated with benzyl benzoate have been reported in the English literature and smaller series of cases in this country. Of the many thousands of cases reported, no mention is made of untoward reactions from its use in the treatment of scabies.⁵ That alone should arouse skepticism, as there is probably no known medication used locally that does not produce a certain percentage of at least local reactions. One writer reports 8,000 cases of scabies without a serious skin reaction.

Benzyl benzoate is being used rather widely in the treatment of scabies among military personnel. I have used Benylate⁶ exclusively in the treatment of scabies for several months. The results on the whole have been satisfactory. Many minor skin irritations of short duration were observed, but in 4 cases the reactions were classified as severe. The treatment was carried out essentially as described by previous writers and by the various companies⁷ producing such preparations. However, the affected individuals were isolated in the sick bay or hospital for the period of treatment. This form of treatment proved an effective method and it was not necessary to repeat the treatment in any case.

REPORT OF CASES

CASE 1.—K. M. presented a history of intense itching for a period of one week. The itching was more noticeable at night or following a warm bath. A rash had been present for five days.

6. Benylate is composed of benzyl benzoate 25 per cent, emulsified in an aqueous solution of triethanolamide stearate. George A. Breen & Co., Kansas City, Mo.

7. A personal communication with Burroughs Wellcome & Company (U. S. A.), New York, Jan. 12, 1944. A personal communication with George A. Breen & Co., Inc., Kansas City, Mo., Jan. 11, 1944.

Examination revealed scattered papular, papulovesicular and excoriated lesions over the body and extremities. The lesions were more diffuse between the fingers, in the axilla and on the penis.

Treatment consisted in a thorough warm soap bath followed by thorough application of Benylate to the entire skin surface with the exception of the face and head. The original application was let dry and Benylate was reapplied in five or ten minutes. All contaminated clothing and bed linens were discarded. After a period of twenty-four hours the medication was removed by means of another warm soap bath.

The patient complained of some smarting while the medication was being applied; however, the discomfort soon disappeared and the patient spent a comfortable night. About twelve hours later the patient was awakened with an intense burning and itching sensation and on examining himself he noticed a fine rash over the entire area to which the Benylate had been applied.

The dermatitis had a typical scarlatiniform appearance. A dermatologist and a member of the local health department were unable definitely to rule out scarlet fever. However, because of the history, absence of fever and other systemic manifestations it was agreed that the condition was a local drug reaction.

The pruritic-dermatitis produced considerable discomfort for a period of ten days and then faded rapidly. There was no exfoliation of the skin following disappearance of the dermatitis.

CASE 2.—O. T. was seen with typical scabies. The history and physical findings were almost identically those of case 1. The treatment was as previously elaborated. Twenty hours after the application of Benylate the itching increased and the patient noticed what he described as a "prickly heat" over the skin surface to which the medication had been applied. Examination revealed the type of rash described in case 1. The secondary rash was treated symptomatically and it began to disappear on the sixth day. Diagnosis of a local drug reaction was made by exclusion.

CASE 3.—J. M., a young white man, was treated for scabies as previously described. Fourteen hours after treatment was instituted he began to experience intense itching and burning. He observed what he described as a "wind burn" rash on the arms, legs and to a lesser extent on the body. Physical examination revealed a flushed appearance to the skin and a very fine, erythematous papular rash, which was quite prominent over the extensor surface of the extremities and to a lesser extent on the remainder of the skin surface. Symptomatic treatment was instituted after removal of the offending agent. The pruritic dermatitis persisted for five days and then slowly faded.

CASE 4.—R. T., a young sailor, was given the benzyl benzoate rapid treatment for scabies. Sixteen hours after the initial application of the medication the patient reported that his "itch" was worse. Examination revealed a rather diffuse, large, red, scaly and slightly elevated rash over the entire body and the extremities. The offending agent was removed and a bland antipruritic ointment was applied. Ten days later the dermatitis began gradually to subside. The patient's final statement was "I'd rather have the itch than the treatment."

SUMMARY AND CONCLUSIONS

Benzyl benzoate is a rapidly effective sarcopticide. It is worthy of continued use especially among military personnel. Let it not be forgotten that troublesome local skin reactions do occur. Patients should be warned to discontinue treatment immediately if the rash and itching become worse. The unwarned patient's tendency is to apply more medicine if the itching does not cease immediately.

In the 4 cases reported the local drug reaction was severe as compared to the disease for which it was used. In case 4 there was a history of previous skin allergy; however, in the other 3 cases there was no history suggestive of previous allergic manifestations.

1015 North Ninth Avenue East.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., Secretary.

YEAST EXTRACT CONTAINING VITAMIN B COMPLEX (See New and Nonofficial Remedies, 1944, p. 606).

The following dosage form has been accepted:

MEAD JOHNSON & CO., EVANSVILLE, IND.

Brewers' Yeast Powder: 28.35 Gm. (11 level teaspoons or 3 level tablespoons). Each gram contains not less than thiamine (vitamin B₁) 0.18 mg., riboflavin (vitamin G) 0.06 mg. and niacin 0.4 mg., together with other factors of the vitamin B complex commonly occurring in brewers' yeast. Dosage for infants, ½ to 1 level teaspoon in the milk formula. For children 1 to 6, 1 to 2 level teaspoons in milk or tomato juice. For use as a supplement in the treatment of deficiencies of various factors of the vitamin B complex, dosage will depend on the type of specific vitamin therapy employed, the severity of the condition and the individual patient; in general, 2 to 4 level teaspoons daily. For supplementary use with specific vitamin therapy in ariboflavinosis and pellagra, 7 or more level teaspoons daily.

Brewers' Yeast Tablets: 0.4 Gm. Each tablet contains 0.4 Gm. dehydrated brewers' yeast supplying thiamine hydrochloride 0.06 mg., riboflavin 0.02 mg. and 0.15 mg. niacin together with other factors of the vitamin B complex commonly occurring in brewers' yeast. Dosage for children, 6 to 10 tablets daily; for adults, 10 to 12 daily; for pregnancy and lactation, 12 to 20 tablets daily. For use as a supplement in the treatment of deficiencies of various factors of the vitamin B complex, dosage will depend on the type of specific vitamin therapy employed, the severity of the condition and the individual patient; in general, 8 to 20 tablets daily. For supplementary use with specific vitamin therapy in ariboflavinosis and pellagra, 35 or more tablets daily.

Preparation—

Mead's brewers' yeast powder is a dried, nonviable strain of *Saccharomyces cerevisiae*, cultured especially for its vitamin content. It is readily suspended in water, milk, tomato juice or other suitable fluids.

PENICILLIN (See THE JOURNAL, Oct. 7, 1944, p. 367).

The following dosage forms have been accepted:

THE UPJOHN COMPANY, KALAMAZOO, MICH.

Penicillin Sodium: Vials containing 100,000 Oxford units.

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Ampuls Penicillin (Sodium Salt): 25,000 Oxford units and 100,000 Oxford units.

E. R. SQUIBB & SONS, NEW YORK

Penicillin Calcium: 100,000 Oxford units.

SCHENLEY LABORATORIES, INC., LAWRENCEBURG, IND.

Penicillin (Sodium Salt): 25 cc. vials containing 100,000 Oxford units.

THEOPHYLLINE (See New and Nonofficial Remedies, 1944, p. 372).

The following dosage form has been accepted:

MERCK & CO., INC., RAHWAY, N. J.

Theophylline (Powder): 30 Gm., 124 Gm. and 498 Gm. bottles.

THEOPHYLLINE ETHYLENEDIAMINE (See New and Nonofficial Remedies, 1944, p. 373).

The following dosage form has been accepted:

MERCK & CO., INC., RAHWAY, N. J.

Theophylline Ethylenediamine (Powder): 30 Gm., 124 Gm. and 498 Gm. bottles

SULFARSPHENAMINE (See New and Nonofficial Remedies, 1944, p. 218).

The following additional dosage form has been accepted:

MERCK & CO., INC., RAHWAY, N. J.

Ampuls Sulfarsphenamine: 0.5 Gm.

SATURDAY, JANUARY 13, 1945

DEATHS OF PHYSICIANS IN 1944

The obituaries of 3,172 physicians were published in *THE JOURNAL* during 1944. The American Medical Directory Report Service recorded 3,415 deaths of physicians in the United States and possessions, or 243 more deaths than obituaries published in *THE JOURNAL*.

Estimation of the net increase to the profession is difficult because of the varying times of graduation in medical schools through the accelerated program introduced in 1942. However, the graduates from July 1, 1943 to the end of 1944 approximated more than 10,000, suggesting a substantial increase to the profession. The majority of this group will enter military service.

Age.—The average age at death was 65.3 in 1944 as compared with 65.2 in 1943 for 3,156 deaths published in *THE JOURNAL*. Fifty-five physicians died between the ages of 25 and 29, 98 between 30 and 34, 73 between 35 and 39, 78 between 40 and 44, 119 between 45 and 49, 157 between 50 and 54, 267 between 55 and 59, 385 between 60 and 64, 523 between 65 and 69, 517 between 70 and 74, 421 between 75 and 79, 286 between 80 and 84, 138 between 85 and 89, 44 between 90 and 94 and 11 between 95 and 100.

Causes.—Heart disease continues to lead the causes of death among physicians. In compiling these statistics, the usual procedure of including primary causes and contributory factors was followed. Coronary thrombosis and occlusion were responsible for 638 deaths in 1944 as compared with 598 in 1943; 250 occurred in the age group 60 to 69. Diseases of the myocardium and pericardium totaled 193, angina pectoris and other coronary diseases 135, chronic heart valvular and rheumatic heart disease 28, subacute bacterial endocarditis (except rheumatic fever) 4 and other diseases of the heart 403. Cerebral hemorrhage, thrombosis and embolism were responsible for 366 deaths, arteriosclerosis for 186 and cardiovascular diseases for 72. Cancer and tumors accounted for 344 deaths, 135 of which were classified under cancer of the gastrointestinal tract.

Two hundred and thirty-eight deaths were attributed to pneumonia, of which 11 were atypical or virus pneumonia. Chronic nephritis and uremia accounted for 125 deaths and acute nephritis for 17. Diseases of the circulatory system were responsible for 81 deaths, diabetes 52, Hodgkin's disease and leukemia 32, pernicious anemia 10 and other diseases of the blood 13, diseases of the gastrointestinal tract 31, cirrhosis of the liver 34 and other diseases of the liver 3, tuberculosis 34, diseases of the respiratory system 23, peptic ulcer (ulcer of the stomach and duodenum) 22, peritonitis 19, influenza 19, pulmonary embolism and thrombosis 17 and other embolism and thrombosis 11, aneurysm 5, diseases of the gallbladder (bile duct) 11, diseases of the nervous system 17, diseases of the prostate 15, asthma 14, appendicitis 5, hernia, chronic arthritis, diseases of the bones and organs of locomotion, encephalitis, syphilis and abscess 4 each, diseases of the spinal cord 3, and diseases of the genitourinary tract 3, alcoholism 2, bacteria, septicemia and pyemia 2 and other infectious diseases 2. There were 4 deaths from epidemic hepatitis, 2 from typhus, 3 from *tsutsugamushi* fever, 1 from undulant fever, 1 dementia precox, 1 Rocky Mountain spotted fever, 1 pellagra, 1 typhoid, 1 hiccup, 1 obstructive jaundice, 2 in which aplastic anemia was attributed to x-ray and radium emanation, 1 glioma, 1 actinomycosis and 1 allergy. Senility was returned as a cause in 35 deaths and 10 were classified as ill defined. There were 38 deaths following an operation and 25 for which causes were not returned.

Accidental Deaths.—Of 138 accidental deaths, automobile accidents accounted for 58. Of the 21 deaths involved in falls, 13 specified fractures of the hip, skull and femur. Of the unusual accidents, 1 physician was killed when an elevator from which he was alighting started upward and crushed him, 1 died of injuries received when a team of horses he was driving ran away, 1 died as the result of a stray bullet that struck him while hunting, 1 was instantly killed by the accidental discharge of his shotgun when he stumbled over a wire, 1 died of burns received when an oil stove exploded, 1 of injuries received when his horse rolled over him and 1 of injuries received when caught by a power saw.

Suicides and Homicides.—Of the 41 suicides recorded, 24 died as a result of bullet wounds, 1 using this method after he had attempted death by illuminating gas and narcotics. Next in order of method used was drugs 6, poisoning 3, hanging 3, carbon monoxide, cut artery and drowning 1 each, "respiratory strangulation" 1 and "fall from roof" 1. Shooting was the method used in the 4 homicides reported.

Miscellaneous Positions.—Among the decedents were 310 who had been teachers in medical schools, 143 of whom had reached the professorial rank. There were 5 deans, 121 members of boards of education, 4 teachers

in a public school and 1 school superintendent. Two hundred and twenty had been health officers, 146 members of boards of health and 24 members of boards of medical examiners. One served as lieutenant governor of Louisiana, 1 as surgeon general of the commonwealth of Massachusetts with the rank of brigadier general, and 34 members of their state legislatures. One had been consul to the Bahama Islands, 1 the Italian consul at Mexico City and 1 a member of the Revision Committee of the U. S. Pharmacopeia.

Association Officers.—The decedents included 1 physician who had been Vice President, 1 Trustee, 1 Council member, 1 honorary life member of a council, 8 section officers and 34 members of the House of Delegates. Forty-five had been presidents of their state societies and 1 secretary. Two hundred and thirty-seven had served as president of their county medical societies and 1 had been president-elect.

Killed in Action

The 3,172 obituaries included 70 physicians who were killed in action during World War II and 113 who died while in military service. In addition, 1 U. S. Public Health Service officer aged 31 died of tsutsugamushi fever while engaged in special war research. Of the group killed in action, specific information was not available in most cases on the type of death; 2 were said to have died of chest wounds, 1 from multiple wounds and 1 from shrapnel severing the spinal cord. A number had first been reported missing in action and subsequently given a presumptive date of death. Theaters of operation designated in official reports as those where injuries resulting in death occurred were the Pacific area 17, European area 10, France 12, Italy 5, North Africa 6, Atlantic area 3, Anzio beach head 3, Normandy 2, Bougainville, Marshall Islands, Isle of Capri, Guam, Tarawa, Coral Sea, Savo Island and Sicily each 1, and 1 died en route from Tunisia to Sicily. Location was not mentioned in 3 obituaries. Of the physicians who were killed in action 26 died in the age group 25 and 29, 33 between 30 and 34, 8 between 35 and 39, 2 between 40 and 44 and 1 between 45 and 49.

Died in Military Service.—Of the 113 physicians who died while in military service, airplane accidents caused the deaths of 20, coronary occlusion 9, coronary thrombosis 5, coronary disease 1, myocarditis 3, heart disease 3, bullet wounds 3, automobile accidents 8, skull fractures 3, malaria 3, accidental drowning 4, parachute accidents 2, meningitis 2, carbon monoxide 2, typhus 2, "gangrene" 2, "extensive multiple injuries" 2, cerebral hemorrhage 2 and 2 died following an operation. One death each was recorded for the classifications of acute morphinism, Hodgkin's disease, malaria, malignant hypertension, Rocky Mountain spotted fever, "died at sea," peritonitis resulting from a bite, atrophy of the

liver, bronchopneumonia, primary atypical pneumonia, accidental asphyxiation, acute hemorrhagic purpura, myelogenous leukemia, injuries received when a boiler exploded, pneumonitis complicated by bronchial asthma, agranulocytosis, respiratory strangulation, "exsanguination," tuberculosis, accidental burns incurred during an explosion when stepping on the starter of a vehicle, and 2 tsutsugamushi fever, 1 of which was complicated with malaria. One each was reported for carcinoma of the liver, sigmoid, brain and intestine and 2 of the stomach. There were 5 suicides and 4 deaths for which no cause was given. Twenty died in the ages between 25 and 29, 33 between 30 and 34, 27 between 35 and 39, 15 between 40 and 44, 8 between 45 and 49, 5 between 50 and 54 and 5 between 55 and 59.

Since the outbreak of World War II THE JOURNAL has recorded the deaths of 101 physicians who died in action and 255 who died while in military service. THE JOURNAL again affirms its opinion that the group of published military deaths does not reflect a true picture of the situation as a whole. The notices received probably represent only a certain proportion of the deaths recorded in Washington and not yet released for publication.

RURAL HOSPITALIZATION AND MEDICAL CARE

At the third war conference of the American Hospital Association at Cleveland in October four papers on rural hospitalization offered much of interest to the physician, the hospital administrator and the social planner.

Carroll P. Streeter,¹ managing editor of the *Farm Journal*, showed that rural areas demand health facilities equal to those of the cities, without charity and without compulsory health insurance. The farmers want better health service, preventive and curative, and they want to have a part in planning it. They want to pay for it on a voluntary, cooperative basis, according to Mr. Streeter. In support of his plea, he points out that farmers are now cooperating successfully in 2,742 buying cooperatives with 1,270,000 members and 600 million dollars worth of goods and services purchased. Moreover, he indicated that farmers have had "mutual irrigation companies, associations for the artificial breeding of dairy cattle, orchard spray rings, cooperative creameries, elevators and livestock shipping associations, farm loan associations, machinery cooperatives, mutual telephone companies, rural electrification cooperatives and half a hundred others." Farmers participating in the Farm Security Administration plans have shown that they are good buyers of health insurance. In conclusion, Mr. Streeter says "Farm folks will invariably

1. Streeter, C. P.: Farmers Want a Health Program. This and the other articles cited were read before the American Hospital Association third war conference, Cleveland, during October 1944.

surprise you. . . . You will be surprised at how well informed, intelligent, progressive and sound in their judgment they are. . . . They won't know much about hospitals or hospital care, of course, but they will have the most worthwhile idea of anybody on what they need, what they want and how they want to pay for it. They can communicate the plan to the people whom they represent with less sales resistance than you can."

Mrs. Jerome Evanson,² state director of education, North Dakota Farmers Union, writes on organized planning as the great need in rural health. She points out that doctors as well as other human beings must seek areas where they can make a living. Rural areas, to attract doctors, must provide (1) assurance of income, (2) modern facilities to attract physicians, (3) opportunities for study and research. She might well have added opportunities for companionship with people of like interests, opportunities for social and cultural life and opportunities for the education of their children. She calls also for public health services, including maternal and child health programs, rural sanitation, health clinics, mobile units for immunization, public health nurses and a nutrition program. All these are in addition to rural hospitals. She calls for hospitals, public health services, physician's offices and dental offices to be brought together under one roof, serving the people as a health center with modern diagnostic facilities. She pays tribute to the Blue Cross plan but says that it has been too costly for the great majority of farm families. Like the previous speaker, she praised consumer cooperative types of development but, unlike the previous speaker, she believes that "if the education of the child is the responsibility of the government then surely the health of the child should be a government responsibility."

Kenneth E. Pohlmann,³ senior health services specialist, Farm Security Administration, called particular attention to the needs of the medically indigent in rural areas. The utilization of hospital care, physician services, surgery and specialist care tends to be lower in rural areas than in urban areas, even in the same income groups. Part of this is due to psychologic attitudes among farm people, who still tend to regard the hospital as a place to die in and a physician as some one to avoid except during critical emergencies. The author, however, believes that "if these attitudes are thoroughly analyzed they are found to spring from an adjustment to customary lacks. They are defense mechanisms that have naturally developed in the face of inadequate resources, which in turn spring from the economic and geographic difficulties prevailing." He discussed the Federal Security Administration program at some length and supported the recent statement by the Subcommittee

on Medical Care of the Committee on Administrative Practice of the American Public Health Association in these words: "The opponents of that statement will have to admit the validity of much that is said." He regards the Farm Security Administration prepayment plans for medical and hospital service as of great benefit but considers them inadequate, incomplete and fragmentary. He concludes:

Rural people want more hospitals and health centers, though they are not always sure as to what they must do to get them; they are asking for due consideration to the needs of rural areas in the distribution of surplus medical and dental equipment now held for war purposes. They want an expanded program of public health through the establishment of more district and county health units. They also want more adequate distribution of medical and dental personnel as between rural and urban areas

The fourth contribution to this symposium was the story of the Hillsdale Community Health Center, Hillsdale, Mich., by Harold F. Stock,⁴ president of the board of trustees of the Hillsdale Community Health Center. Mr. Stock makes a great many points, some accepted and some controversial. Briefly, they are as follows:

1. Place hospital facilities at the disposal of health departments.
2. Make visiting nurse service available to every home in the county.
3. Cooperate with home maternity instruction and nursing.
4. Extend diagnostic services at very low rates.
5. Give low patient rates and pay high wages.
6. Form an active woman's auxiliary.
7. Establish a private fund for charity patients.
8. Provide consolidated medical clinics for all the town's physicians.
9. Perform laboratory services for the public health department.
10. Admit patients of osteopaths.
11. Operate a dental clinic.
12. Promote hospital and medical service plans "as the logical answer to the anarchistic cry for socialized medicine. Let's socialize our own medicine! In 1940, hospital service insurance was practically nonexistent; today 10,440 of the county's 28,000 people are protected (in Hillsdale County—Ed.).

The articles in this symposium indicate that the people in the rural regions are awake to the need of equalization between the health service they now have and that which is enjoyed in urban areas. They are not disposed to look to the government except as a last resort. As Mr. Streeter points out, "Most farmers of the United States are in revolt against government planning, government interference with their private lives and businesses (except as war makes necessary) and government paternalism. They want the government to run as few things as possible and they think that it runs too much now. They are fed up with the AAA and the OPA." They are ready to cooperate with hospital and medical leadership. They are willing, apparently, to be technically advised as to ways and means of obtaining their objective, which is better hospital and medical service and more of it at prices which

they can afford to pay and on a basis of independent self reliance. The best way to forestall government control of medical services is to keep that control in the hands of local people. The ideas expressed appear to offer a wide open door of opportunity for medical societies in the rural areas and especially for state medical societies in predominantly rural states.

Current Comment

SOME TOXIC ASPECTS OF DIGITALIS THERAPY

Digitalis preparations are used extensively in the treatment of heart disease. In obesity they have been used to reduce food intake and weight by causing loss of appetite. Their use in ointments for the treatment of indolent ulcers and for protection against the lethal effect of high altitude has been suggested. Probably their medicinal use may have unintended toxic by-effects. The toxic action of digitalis glycosides on the cardiac function has been fraudulently used to cause simulation of heart disease for the collection of life insurance. While physicians are usually well acquainted with the functional cardiovascular and cerebral manifestations of digitalis poisoning, they are less familiar with some recent clinical and experimental evidence pointing to the induction of anatomic cardiovascular and cerebral reactions and hematic effects which are of medical and medicolegal significance. Experimental subjection of animals of different species to lethal and sublethal doses of digitalis glycosides resulted in myocardial hemorrhages, necrosis and fibrosis as well as in cerebral degenerations, necrosis and gliosis.¹ Travell and her associates² were unable to demonstrate in patients receiving large oral doses of digitalis for varying periods of time any myocardial hemorrhages at necropsy, but the occurrence of myocardial and cerebral lesions in man as the result of digitalis poisoning is nevertheless suggested by the resulting functional disturbances. Gilbert, Trump and de Takats³ observed an increased incidence of thrombosis in cases treated with digitalis and found that the clotting time was appreciably shortened following its use. Confirmatory results are reported by Massie and his co-workers,⁴ who suggest that digitaloids exert a thromboplastic action. Digitalis glycosides are saponin-like substances; crude digitalis preparations contain appreciable quantities of saponins, which may favor thrombosis by their effects on the vascular wall.

HEALTH INSTRUCTION IN OREGON HIGH SCHOOLS

Increased interest in health instruction in the nation's schools is apparent in a syllabus just received from the Oregon State Department of Health.¹ This material is organized in two parts: Part I concerns the identification of the major health problems of living. First is a consideration of the administrative aspects of school health education. This is followed by material, largely in question form, outlining the principal problems, which include care of the body to promote health and to improve the appearance; the development and maintenance of organic vigor and functional body symmetry through play and recreation, plus similar units on diet, communicable diseases, accident prevention, social living, sex, consumer problems and healthful community environment. A useful section tells how to develop the school library on a limited budget. Part II consists of health guide units similar to the sample included in part I and is obviously intended for classroom use. Part III is still in preparation; it is described as "a discussion of the twelve year public school health instruction program in Oregon, including an example of a health scope and sequence chart." Accompanying these basic materials are supplementary manuals issued as part of a series² by a subcommittee of the Oregon State Joint Committee for Health and Physical Fitness. This joint committee has been studying the problems of health and the school population for five years. It includes representatives of the state department of education, the state board of health and the state system of higher education. It has worked through subcommittees, one of which prepared a manual on health services for the school age child in Oregon, another the "Oregon Manual for the Use of the School Health Record Card" and a third a manual on the school lunch. These supplementary manuals are brief, convenient and yet complete. The cooperation between state departments of health, state departments of education and colleges in the state, as exemplified in the Oregon study and the results now beginning to come out of it, is significant for the stimulus it gives to health education at the secondary school level, where health education has long been the stepchild of the curriculum. Perhaps even greater significance attaches to the cooperation between the state health agency and the state educational authority. This trend is in evidence in a number of states, the Oregon plan being one example of a useful and important trend. The existence of such state health and educational programs should be of tremendous value in the development of the nationwide physical fitness program now being launched by the Joint Committee on Physical Fitness, in which the American Medical Association is participating with representatives of the United States government.

MEDICINE AND THE WAR

ARMY

THE CONTROL OF DENGUE ON SAIPAN

Shortly after the invasion of Saipan an epidemic of dengue fever occurred among the troops employed in the operation. The rapid increase in the incidence of the disease necessitated prompt control measures. The island commander, on recommendation of the surgeon, designated each unit commander as responsible for the elimination of mosquito breeding within his assigned area and its immediate vicinity. Under the direct supervision of the surgeon a sanitary company undertook mosquito survey and control work in the more thickly populated areas.

The portions of the island inhabited by our military forces were mapped and segmented as to areas of importance. Tremendous quantities of debris were removed and vast areas were cleared. Water pools were oiled, water containers were emptied or otherwise protected from mosquito breeding and tree holes were filled with dirt. All measures for mosquito protection were enforced to the utmost. A solution of DDT was used extensively as an insecticidal spray disseminated by mechanical power sprayers and by airplane. All tents, living quarters and mosquito bars over a wide area were sprayed for a residual effect. Area spraying by aircraft was thoroughly exploited over wide territories. The effects of these procedures were dramatic. The reduction in the larval and adult mosquito population and in the flying population was enormous. Within two weeks of the onset of the control program daily admission of new cases of dengue fell more than 80 per cent, and progressive improvement has occurred since that time.

This experience serves to reemphasize the effectiveness of command action in disease prevention when promptly utilized and efficiently employed under Medical Department recommendations. It further attests the value of DDT as an adjunct to other sanitary measures in the control of insect borne diseases.

NEW AWARD AUTHORIZED FOR ASSAULT SOLDIERS

A new service award for army personnel who participate in a combat parachute jump, combat glider landing or initial assault landing on a hostile shore was recently announced by the War Department. The device is a bronze Indian arrowhead $\frac{1}{4}$ inch high. It will be worn in a vertical position with the point upward on the theater service ribbon which indicates the area in which it was earned. Only one arrowhead will be worn on any theater ribbon. To qualify for the award, officers or enlisted men must take a parachute jump or glider landing in enemy held territory as a member of a force carrying out an assigned mission or take part in the assault waves of an amphibious landing on enemy held shores. Commanders of organizations engaging in assaults of this nature will forward recommendations to the theater commander as soon as practicable after the action has taken place. The arrowhead will be awarded to all personnel who have taken part in any such operation since the start of the war. In order to determine which units in their commands have eligible personnel, theater commanders will review all operations since Dec. 7, 1941. Any eligible individual who is no longer a member of the organization with which the award was earned may obtain an arrowhead by submitting an affidavit to his present commanding officer. Persons who are no longer in the Army should submit an affidavit to any post or camp commander.

CONSULTANT IN MEDICINE OF THIRD SERVICE COMMAND

Col. John Minor, former chief of the medical service, Woodrow Wilson General Hospital, Staunton, Va., has been appointed consultant in medicine of the Third Service Command, Baltimore.

NEW POSITIONS OPEN FOR EXPERT LIMB FITTERS

Army amputation centers in this country are in immediate need of expert limb fitters. Civilians with the necessary technical background in manufacturing, adapting, repairing or fitting orthopedic appliances are being urged by the Army Medical Department to qualify for the newly created positions of "orthopedic technical advisers." These are Civil Service positions.

A technical adviser grade P-4 receives a yearly salary of \$4,428 for a forty-eight hour week. He serves as consultant and adviser to the orthopedic surgeon on the design and construction of artificial limbs and counsels individual amputees on their use. A technical adviser grade P-3 receives a yearly salary of \$3,823 for a forty-eight hour week and acts as assistant, performing specific research, designing and fitting limbs and training enlisted shop personnel.

Orthopedic shops are located at the six Army general hospitals which are amputation centers: Bushnell General Hospital, Brigham City, Utah; Thomas M. England General Hospital, Atlantic City, N. J.; Percy Jones General Hospital, Battle Creek, Mich.; Lawson General Hospital, Atlanta, Ga.; McCloskey General Hospital, Temple, Texas, and Walter Reed General Hospital, Washington, D. C.

Inquiries should be directed to the Civil Service Commission or the Office of the Surgeon General, Washington 25, D. C.

MEMBERS OF TWENTIETH GENERAL HOSPITAL TO VIEW HOME MOVIES

A special nine reel motion picture was recently planned, directed and filmed by Dr. Louis H. Twyeffort, Wynnewood, Pa., an instructor in psychiatry at the University of Pennsylvania School of Medicine, Philadelphia, and sent to the 20th General Hospital Unit in India as a surprise Christmas gift from friends at the University of Pennsylvania, where the hospital unit was organized. Three reels show members of the families of medical men, dentists and others serving with the unit, two are devoted to families of nurses, and the remaining four recall personalities and places well known to all who have been associated with the university's medical divisions. When the 20th General Hospital left the University of Pennsylvania for active service early in 1942 the unit included approximately sixty physicians, surgeons, dentists and other officers and more than a hundred nurses.

SURGICAL CONSULTANT TO THE SECRETARY OF WAR

Dr. Sterling Bunnell of San Francisco, noted as an authority on surgery of the hand, has been appointed surgical consultant to the Secretary of War. He reported to Washington November 30, and his first tour included Cushing General Hospital, Framingham, Mass., England General Hospital, Atlantic City, Valley Forge General Hospital, Phoenixville, Pa., Newton D. Baker General Hospital, Martinsburg, W. Va., and Wakeman General Hospital, Camp Atterbury, Indiana.

CHIEF NURSES GRADUATE AT SCHOOL OF AVIATION MEDICINE

Twenty-six "chief nurses" recently graduated at the AAF School of Aviation Medicine, Randolph Field, Texas. The graduates are from Air Forces installations throughout the nation and have completed a course in the administrative as well as professional aspects of the position of chief nurse for a period of four weeks. Col. John R. McGraw, acting assistant commandant of the school, presented the diplomas.

RECRUITING STUDENT PHYSICAL THERAPISTS

Recruiting of student physical therapists has been started by the War Department. After an apprenticeship in army hospitals qualified graduates will be commissioned as second lieutenants in the Medical Department. Applicants must be under 38 years of age, must be college graduates with a major in physical education or biologic science, must meet citizenship and physical requirements and must have no dependent children under 14 years of age. Such applicants will start at a salary of \$1,440 a year; on satisfactory completion of six months' training in army general hospitals, students become apprentice physical therapy aides at a yearly salary of \$1,620. Applicants who have had a similar course in civilian institutions will be eligible for this position. On satisfactory completion of their apprenticeship they will be commissioned as second lieutenants. They may be placed on duty overseas or in this country.

WAC RECRUITMENT TO CONTINUE IN 1945

The War Department recently announced that the army will continue to recruit for the Women's Army Corps in 1945. Because of the increasingly high casualty lists and the return of thousands of sick and wounded soldiers to the United States, together with a critical shortage of army nurses, there is an urgent continuing need for several thousand medical and surgical technicians in army hospitals. This need is acute and must be filled. Women enlisted in the WAC for this duty will receive specialized training designed to fit them as enlisted technicians and are assured duty in army hospital wards aiding in the care of sick, injured and wounded soldiers. Other enlisted technicians needed by the Army Medical Department include pharmacists, laboratory technicians, dental technicians and psychiatric social workers.

COMBAT PAY FOR MEDICAL UNITS

Many will welcome assurance that the War Department is giving its attention to additional recognition for men of the Medical Corps serving with combat units. General Eisenhower has recommended to visiting congressmen, says a report from France, that he be given extra combat pay comparable to that of the combat unit he serves.

Secretary Stimson indicates that the case of the man of the Medical Corps presents a separate problem because of his non-combat status under the Geneva Convention, but separate insignia and a separate pay system would seem to clear that hurdle. The Secretary noted also that more Medical Corps men receive technical ratings, thus boosting average pay, but that doesn't help the medic who hasn't his rating or compensate the corps generally when it leaves a safe spot for the shooting front.

TUBERCULOSIS IN THE ARMY

The incidence of tuberculosis, as reflected by the annual hospital admission rate, is only one tenth as high in the Army now as it was in the first world war. The principal factor in the decrease in the army rate is the screening process which is in operation to exclude men with active or potentially active tuberculosis before they are inducted into the Army, Col. E. R. Long, chief consultant on tuberculosis for the Surgeon General's Office, pointed out. Another reason is the fact that among the civilian population tuberculosis is only one third as prevalent now as it was during the first world war.

MAJOR GORDON H. HAGGARD MISSING IN ACTION

Major Gordon H. Haggard, formerly of Hope, Ind., has been reported missing in action since October 7. Dr. Haggard was a flight surgeon with a heavy bombardment group and is listed as missing in action over Germany. He graduated from Indiana University School of Medicine, Indianapolis, in 1933 and entered the service March 27, 1941.

FOURTEENTH CLASS OF AVIATION PHYSIOLOGISTS

Graduation exercises at the School of Aviation Medicine, Randolph Field, Texas, for the fourteenth class of Aviation Physiologists were held December 16. Col. Paul A. Campbell presented the certificates. The course in aviation physiology is of five weeks' duration and treats of the effects of lowered barometric pressure on personnel, anoxia and the effects of flight on man, the operation of low pressure chambers, the theory and practical use of oxygen equipment and the conduct of high altitude indoctrination and classification.

ARMY AWARDS AND COMMENDATIONS

Captain Seymour Reissman

Capt. Seymour Reissman, formerly of Brooklyn, was recently awarded the Bronze Star Medal "for heroic action near — on July 19, 1943. Captain Reissman and his crew dismounted from their medical half track to inspect the vehicle when enemy artillery fire started falling approximately 200 yards away. All of the personnel immediately took cover. When it became apparent that the fire was creeping toward the half track and would destroy it if it was not moved, Captain Reissman promptly and with complete disregard for his own safety ran to his vehicle and, on foot, guided his driver in backing the vehicle approximately 100 yards to a position of safety. During this time artillery fire was falling on both sides of the road opposite the half track. The immediate and courageous action on the part of Captain Reissman undoubtedly saved the vehicle from destruction and reflects high credit on himself and on the military service." Dr. Reissman graduated from the Long Island College of Medicine, Brooklyn, in 1938 and entered the service Oct. 25, 1940.

Captain Maurice Stamler

The Bronze Star Medal was recently awarded to Capt. Maurice Stamler, formerly of Beardstown, Ill. The citation read "On Oct. 26, 1943 in Italy he moved through an enemy artillery concentration which was falling at the rate of eight rounds per minute to the aid of three seriously wounded infantrymen who had been struck by fragments of an enemy shell. Arriving some time before his ambulance he worked forty-five minutes with enemy shells bursting within 50 yards of him, administering aid to these wounded men. On arrival of the ambulance after the enemy artillery fire had ceased he directed their evacuation. His utter disregard for personal safety in this gallant action is deserving of the highest praise." Dr. Stamler graduated from the University of Illinois College of Medicine, Chicago, in 1934 and entered the service Aug. 21, 1941.

Captain Roy E. Hanford

Capt. Roy E. Hanford, formerly of Sandpoint, Idaho, has been awarded the Bronze Star Medal. The citation accompanying the award reads "During an intense enemy artillery barrage on April 6, 1944 near Anzio, Italy, a detachment tent of a hospital was struck by an enemy shell. With other medical officers who were on duty with him at an adjacent hospital he immediately rushed to the scene of the shelling and administered treatment to a number of seriously wounded soldiers. Although the area was under continuous bombardment they remained at the perilous task of rendering medical aid and expediting the quick removal of casualties for additional treatment. Their heroic performance reflects the finest traditions of the Medical Corps." Dr. Hanford graduated from Northwestern University Medical School, Chicago, in 1941 and entered the service July 1, 1942.

Captain Isbin S. Giddens

The Bronze Star Medal was recently awarded to Capt. Isbin S. Giddens, formerly of Ray City, Ga., whose citation declared that "at New Georgia Island, Solomon Islands, he demonstrated an untiring devotion to duty, high personal courage and a marked degree of professional skill when by prompt action and efficient surgery he saved the life of a soldier who was seriously wounded. He traversed 400 yards of terrain covered by hostile fire to reach the stricken man and, working

in a slit trench during a heavy rain, performed a most difficult suture of the jugular vein. Because the soldier was too weak to move, Captain Giddens remained with him throughout the night, evacuating him the following morning." Dr. Giddens graduated from the University of Georgia School of Medicine, Augusta, in 1933 and entered the service Oct. 19, 1941.

Captain Mark M. Pomaranc

Capt. Mark M. Pomaranc, formerly of Chicago, was recently awarded the Bronze Star Medal. The citation read "At Dutch New Guinea, from April 20 to June 12, 1944, he distinguished himself in the performance of his duty as surgeon of a task force. His untiring efforts in administering to the sick and wounded at advance outposts was a direct contribution to the high combat efficiency of the patrols. Working under hardships in combating jungle diseases, handicapped by supply, evacuation and communication problems, he succeeded in maintaining a high standard of health and sanitation." Dr. Pomaranc graduated from Northwestern University Medical School, Chicago, in 1941 and entered the service Jan. 5, 1942.

Major Martin R. Wisely

The Silver Star Medal was recently awarded to Major Martin R. Wisely, formerly of Edenton, N. C., whose citation declared that "on June 11, 1944 near Carentan, France, while his organization was pinned down by intense enemy machine gun and mortar fire, he, with complete disregard for his personal safety, moved in to the front lines, administering first aid and removing the wounded, thereby saving the lives of many

wounded soldiers. His conduct was in accordance with the highest standards of military service." Dr. Wisely graduated from the University of Virginia Department of Medicine, Charlottesville, in 1935 and entered the service Sept. 16, 1940.

Lieutenant Colonel Ben L. Pentecost

The Soldier's Medal was recently awarded to Lieut. Col. Ben L. Pentecost, formerly of Memphis, for "extraordinary heroism" in a bomber crash on September 3. While rendering first aid, part of the bomb load exploded. Injured, he continued to give medical aid, although not all of the bombs had exploded. "The performance of his duties in the face of unknown dangers reflects the highest credit on this officer and the armed forces of the United States." Dr. Pentecost graduated from the University of Tennessee College of Medicine, Memphis, in 1935 and entered the service Feb. 1, 1941.

Captain Jacob Schnitman

An award of the Bronze Star Medal was recently made to Capt. Jacob Schnitman, formerly of Brooklyn, for meritorious service in combat as a battalion surgeon in Italy, Sept. 10, 1943 to April 16, 1944. The citation reads "By his prompt and efficient treatment of wounded, Captain Schnitman saved countless lives and reduced materially the morbidity and mortality rate. Through his efforts a high degree of combat efficiency has been achieved in his medical detachment." Dr. Schnitman graduated from the University of Basel Faculty of Medicine, Basel, Switzerland, in 1936 and entered the service March 5, 1941.

NAVY

V-12 PROGRAM OF THE NAVY

The Navy has announced that its V-12 program, beginning Nov. 1, 1944, is limited to approximately 1,000 enlisted men from the ranks selected under the program. No trainees from civil life or from the military service will enter the Navy V-12 (college program) in the term starting March 1, 1945. Students already enrolled in the V-12 program under contract to the Navy will continue their training as scheduled. The decision to eliminate any input on March 1, 1945 is the result of the Navy's estimate of its future officer requirements. There are now 69,000 prospective young officers in training in the Navy's V-12 program. Additional examinations will not be held for candidates who desire to follow a premedical course.

CHANGE IN COMMAND AT NAVAL MEDICAL SCHOOL

Capt. Herbert L. Pugh (MC), U.S.N., recently assumed the post of medical officer in command at the Naval Medical School, Bethesda, Md., as relief for Capt. Paul W. Wilson (MC), U.S.N. Prior to his present assignment Dr. Pugh was chief of surgery at the U. S. Naval Hospital, San Diego, Calif. He graduated from the University of Virginia Department of Medicine, Charlottesville, in 1923 and was commissioned a lieutenant (junior grade) in the Medical Corps in 1923 and since that time has had many varied tours of duty both ashore and afloat.

APPOINT PSYCHIATRY EXAMINER

Comdr. F. J. Braceland (MC), U.S.N.R., Neuropsychiatry Branch, Professional Division, Bureau of Medicine and Surgery, has been appointed an examiner on the American Board of Psychiatry. He attended board meetings in New York recently to examine candidates for certification as specialists in psychiatry.

LIEUTENANT COMMANDER WAYNE H. STEWART MISSING IN ACTION

Lieut. Comdr. Wayne H. Stewart, U.S.N.R., formerly of Coraopolis, Pa., has been reported missing in action. Dr. Stewart graduated from the University of Pittsburgh School of Medicine in 1933. He entered the service Nov. 5, 1940.

FIRST SUBMARINE SURGEON

Lieut. Comdr. William S. Francis, formerly of Washington, D. C., is believed to be the first navy doctor to wear both the wings of a flight surgeon and the dolphins of a submarine surgeon. He was, in fact, the first submarine surgeon, for he was appointed the nucleus of a board to qualify other navy doctors for that designation. He recently completed his courses in flight surgery at the Naval Air Training Bases, Pensacola, Fla., and is awaiting assignment. After the United States declared war he was assigned to duty in the South Pacific as a submarine surgeon and there saw activity in the preventive branch of medicine in connection with submarine warfare, salvage operations and rescue work. His duty in the twenty-six months he was in the Pacific area included assignments in the vicinity of Guadalcanal and Tulagi, Hawaii and the Aleutians. In August of 1944 he arrived at Pensacola for training as a flight surgeon. Dr. Francis graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1935 and entered the service Aug. 19, 1937.

MASS CHEMOPROPHYLAXIS AT ALL NAVAL TRAINING STATIONS

Capt. T. J. Carter (MC), U.S.N., chief of the Division of Preventive Medicine, Bureau of Medicine and Surgery, recently stated that as a result of "the largest controlled experiment in the history of medicine" mass chemoprophylaxis against respiratory diseases caused by streptococcal infections has been instituted at all naval training stations. Dr. Carter stated that in 1943 mass chemoprophylaxis involving a million men was undertaken in selected stations on a controlled basis, the result of which was very successful. "At one station the rate of admission for scarlet fever varied from 63.5 per thousand to 171.6 per thousand during the observation period before the use of sulfadiazine. Following the institution of the prophylaxis, the rate fell to zero within two weeks. . . . Tonsillitis at this same station fell from 426 per thousand to 46 per thousand. Rheumatic fever, the most serious of the infections associated with the streptococcus organism because of the heart involvement, was reduced from 87 per thousand to zero within four weeks." Dr. Carter estimated that the experiment alone saved over a million man-days for medical personnel and between 50 and 100 million dollars.

FOUR NAVAL HOSPITALS TO HAVE OCULAR PROSTHETIC UNITS

Expansion of facilities for production of the new acrylic resin artificial eyes developed at the Naval Dental School, Bethesda, Md., recently began with the assignment of four dental officers to the naval hospitals at San Diego and Oakland, Calif., Seattle and Philadelphia. The dental officers will have completed a course in production of the eyes and are assigned to hospitals which already have dental prosthetic units. At the same time four other dental officers were assigned to the course and ten Waves and two enlisted men began special training in painting and coloring the eyes at the Naval Dental School. On completion of the course the enlisted personnel will be assigned to the aforementioned hospitals to assist the dental officers. Each of the hospitals designated will establish maxillofacial (ocular) units in connection with their dental prosthetic facilities.

NAVY AWARDS AND COMMENDATIONS

Lieutenant Irad B. Hardy Jr.

The Navy and Marine Corps Medal was recently awarded to Lieut. Irad B. Hardy Jr., formerly of Boston. Accompanying the award was the following citation, signed by Admiral Chester W. Nimitz: "For extraordinary heroism while serving against enemy Japanese forces on Kwajalein atoll, Marshall Islands, on Jan. 31, 1944. During the early stages of the battle, three LVT's (amphibious tractors) carrying him and forty Marines

capsized on a reef. He, although narrowly escaping death himself, repeatedly swam through the surf, pulling injured and dazed men to a channel marker. After all but seven of the men had reached this point of comparative safety, he, at the risk of his own life, dauntlessly set out over treacherous, submerged reefs for a grounded LCI (landing craft, infantry), which was approximately 200 yards away. He obtained a line from the LCI and courageously brought it back to the men precariously stranded on the marker. He then, although exhausted, directed and assisted the injured men to safety aboard the LCI. By his great personal valor, aggressive leadership and fearless devotion to duty, he saved many lives. His conduct throughout was in keeping with the highest traditions of the Naval Service." Dr. Hardy graduated from Harvard Medical School, Boston, in 1938 and entered the service Sept. 7, 1942.

Lieutenant Peter T. Brooks

Lieut. Peter T. Brooks, formerly of Boston, was recently commended for outstanding services as set forth in the following citation: "For outstanding services rendered to war casualties at Saipan Island, incident to the invasion of that island, June 15-22, 1944. As a medical officer serving aboard an attack transport ship, he worked skillfully and tirelessly administering to wounded men evacuated from the combat zone. His professional skill and steadfast devotion to duty were responsible for saving many lives and were in keeping with the highest tradition of the naval service." Dr. Brooks graduated from Columbia University College of Physicians and Surgeons, New York, in 1942 and entered the service April 15, 1943.

MISCELLANEOUS

AMERICAN LEGION PLANS PROGRAM FOR MEDICAL SERVICE

The American Legion recently announced a program to mobilize the highest medical intelligence of America to advise on the mental and physical health needs of returning veterans. Nine eminent physicians and surgeons were named to a national board that will counsel the Legion in its service to discharged men. They are Col. Leonard G. Rowntree, chief of the selective service division and internationally known authority on glandular disturbances, named as chairman; Major Gen. George F. Lull, deputy surgeon general, U. S. Army, and Rear Admiral William C. Agnew, assistant surgeon general, U. S. Navy, both advisers in general medicine; Col. Esmond R. Long, Office of the Surgeon General, U. S. Army, adviser in pulmonary disease; Capt. Raymond C. Wells, U. S. Navy, assistant chief of the Selective Service Medical Division, adviser in dentistry; Lieut. Col. Louis H. Renfrow, executive officer, Selective Service Medical Division, as assistant chairman of the board; Lieut. Col. Charles W. Mayo, adviser in surgery; Dr. William D. Stroud, professor of cardiology, University of Pennsylvania, adviser in heart ailments, and Dr. Winfred Overholzer, superintendent of St. Elizabeths Hospital, Washington, D. C., adviser in psychiatry. Particular attention will be given by the board to the handling of psychoneurotic cases.

National Commander Edward N. Scheiberling stated that similar medical advisory groups are projected for each state, and it is planned, as the program progresses, to appoint post surgeons in each community having a Legion post.

NUTRITION LABORATORY NOW IN CHICAGO

The Medical Nutrition Laboratory, formerly part of the Army Medical School, Army Medical Center, Washington, D. C., has moved to 1849 West Pershing Road, Chicago 9. Capt. George Berryman, Sn. C., is the acting commanding officer, and Capt. Cyrus French, Sn. C., is executive officer. A new laboratory is being constructed, and the scope of the work will be increased. In addition to training nutrition officers there will be physiologic, chemical and bacteriologic studies made of nutritional problems pertaining to army personnel.

PENICILLIN TREATMENT OF YAWS

The Surgeon General's Office, in cooperation with the Office of the Coordinator of Inter-American Affairs and the Army Epidemiological Board, has organized a joint project in Haiti to study the effect of penicillin in the treatment and control of yaws. Yaws is endemic in certain sections of Haiti, and the large number of cases affords an excellent reservoir of clinical material for study. Lieut. Col. T. H. Sternberg, director, Venereal Disease Control Division, Preventive Medicine Service, Office of the Surgeon General, who has had considerable experience with penicillin, went to Haiti this month to cooperate with the American Sanitary Mission of CIAA under the direction of Lieut. Col. James H. Dwinelle, chief of party, in initiating the project there. He was accompanied by Major Charles R. Rein, serologist from the Army Medical School. The following week Brig. Gen. James S. Simmons, chief of preventive medicine service, and Major Douglass W. Walker, executive officer, visited the group in Haiti to observe the progress of the project and to assist in the development of plans for its continuation. Also with the group in Haiti were Capt. Ralph P. Creer of the medical administrative corps and Corp. Bruno Mickleit of the Medical Arts Service of the Army Medical Museum.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, December 30, page 1157)

MASSACHUSETTS

New England Hospital for Women and Children, Boston. Capacity, 260; admissions, 4,033. Miss Josephine A. Mulville, R.N., Superintendent (6 interns, 1 resident, all women).

NEW YORK

Hospital for Joint Diseases, New York City. Capacity, 362; admissions, 5,311. Dr. J. J. Golub, Director (8 interns, July, August, September, October).

Mount Sinai Hospital, New York City. Capacity, 853; admissions, 14,534. Dr. Joseph Turner, Director (2 residents—otology).

OREGON

Emanuel Hospital, Portland. Capacity, 425; admissions, 11,532. A. L. Morland, Superintendent (2 residents).

SECOND SESSION, FRIDAY AFTERNOON

DR. D. L. CANNON, Montgomery, Ala., Presiding

The Red Cross Blood Procurement Program

DR. OLIN WEST, Chicago: We have here today, as representatives of the American Red Cross, Dr. G. F. McGinnes, who is the medical director of the Red Cross, and Dr. G. Canby Robinson, who has had a large part to play in the establishment of blood banks. They want to get such suggestions and advice as you may be willing to offer as to the program that the Red Cross should adopt and carry forward in the matter of the collection of blood and in the preparation and distribution of plasma.

DR. G. FOARD MCGINNES, Washington, D. C.: All of you are familiar with the Red Cross blood procurement program for the armed forces. Some are probably familiar with the civilian program which we have carried on during the war at the request of certain communities and states to furnish blood donors for civilian purposes. During the past few months our chapters have had requests to continue into some sort of program of blood or donor procurement following the war. It was our thinking that we should consider these requests and, if the Red Cross is to continue in this field, work out some program before our war program ceases. It was brought to the attention of our National Medical Advisory Committee for suggestions. It was its thinking and our thinking that the Red Cross should go into such a program if there is a need. It was our thinking further that before we developed any definite plans we should have the advice and guidance of organized medicine through the American Medical Association and of the state official health agencies through the Association of State and Territorial Health Officers; therefore we met with the Board of Trustees of this Association and at its invitation we are meeting with you today. We have also met with the Association of State Health Officers. We will later discuss this formally or informally with the American Hospital Association. The purpose of this discussion is to get your suggestions and advice regarding the participation of the American National Red Cross in a donor procurement program to meet civilian needs in peacetimes. However, I will appreciate it if Dr. G. Canby Robinson, who is director of our national blood donor program, will give a few of the pros and cons regarding our program. As you know, Dr. Robinson has probably had more experience in this field than any other man has ever had and I certainly hope will ever have in the future.

DR. G. CANBY ROBINSON, Baltimore: The Red Cross has an organization including 3,778 chapters that are organized on a community and county basis. The Red Cross has a rather extensive experience in recruiting blood donors and in the administration of blood donor centers during the war. It is a question as to how this experience may best be employed on a peacetime activity. There has been much enthusiasm and interest developing in a number of localities and cities and communities in regard to having blood and blood derivatives available for the civilian population. The Red Cross chapters are being asked to participate. This program as it seems to be developing may be statewide, it may be communitywide or even projects that involve only a single hospital are suggested. In some instances the local medical societies may sponsor such programs, and in other instances state or municipal departments of health may have funds available for the support and may therefore develop blood and plasma transfusion programs as an official service. The blood donor service, which was instituted at the request of the Surgeons General of the Army and the Navy, is a joint project in which the Red Cross and the Division of Medical Sciences and the National Research Council participate. The technical aspects have been controlled by a small committee of the National Research Council. The Red Cross has not had the responsibility of formulating the technical operations, and the Red Cross does not intend to engage in any such technical operations in the future. Now the relation of the Red Cross to these projects presents two somewhat opposed considerations. The Red Cross desires to serve the public through its chapters in matters of the relief of suffering and the promotion of health and in so doing show itself worthy of the social, spiritual and financial support of the public. Within the limits of its function

as set forth by its Congressional charter, the American Red Cross serves the people of this country in times of peace as well as in times of war. It is anxious to respond through its national organization and its chapters to any worthy public demand for a type of service that falls within the fields of its activities. On the other hand, the Red Cross is mindful of the serious responsibility it assumes in participating in any blood or plasma transfusion program which deals with very serious matters of life and death. In recruiting volunteer donors the Red Cross is concerned with and has the responsibility for their safe and treatment as individuals: the technical standards used in procuring their blood, the care with which the blood is handled and conceived, the proper distribution and use of the blood and observance of all understandings of donors in regard to the charges to be made for its use. The Red Cross is supported by voluntary contributions, and the type of service, the type of reputation and the type of public relations that are maintained determines quite a great deal the public support that the Red Cross has. In all the discussions we should like to have you bear in mind that, although the Red Cross is extremely anxious to do a public service, if there is a need and if the profession feels that it should be done, it must have your consideration and your sympathetic understanding of the problems that are involved when it undertakes the enrolment of donors. We have had three responsibilities before us all the time in the Red Cross blood donor service, the first being the protection of the donor, the second the protection of the blood that is donated and the third the protection of the Red Cross money. We put the third, because our primary responsibility has been the protection of the donor. We are proud of the fact that we have bled 4 or 5 million people and obtained over 10 million pints of blood with an extremely small percentage of accidents and difficulties. The American public is now educated to the value or to the ease, you might say, of giving a pint of blood and the relative safety with which it may be done. We are convinced that the public will respond to any well organized service for the supply of human blood for civilian needs, and the Red Cross hopes that all the organizations with which it cooperates can be so standardized, if we can use that word, or will maintain such good standards of technique and of distribution and of ethical treatment of the whole matter that the Red Cross can go along with these projects.

DISCUSSION

DR. MICHAEL A. TIGHE, Boston: Many of our communities have set up one or two blood banks in the hospitals in those communities. What consideration does the Red Cross intend to give to these blood banks that are already set up for the purpose of meeting civilian needs?

DR. CREIGHTON BARKER, New Haven, Conn.: The Connecticut State Medical Society recognizes the need for the project that Dr. Robinson has outlined—the continuance of a community blood service after the war. Our society at its meeting late in the summer appointed a committee on statewide blood bank for the express purpose of exploring the possibilities of continuing the operation of the blood bank in our state, which has been operated in cooperation with the Red Cross and, I should like to say, in a highly satisfactory manner to us. That association has been pleasant, productive and valuable. About ten days ago we had a meeting with the board of trustees, or a similar body, including the president of the Red Cross chapter where the operation has been centralized in Hartford during the war period, for the express purpose of discussing the problem that is now presented to us, as to how we could as a state medical society on the one hand and the local Red Cross chapters on the other hand continue this useful service. It was our tentative opinion at that time, which received general agreement from the physicians who were present as well as the gentleman from the Red Cross Board, that the technical service should be done by an organization other than the Red Cross, that is, a committee, an operating group, from the state medical society. It would, in fact, be the same individuals who have been carrying on the job for the last three years, with the exception of the loss of one or two naval medical officers who have been temporarily assigned to our program. That personnel is willing and anxious to continue to do it. The gentleman from the Red Cross was of the opinion that perhaps the most useful

thing the Red Cross might do would be, as Dr. Robinson has proposed, the recruiting of donors and certain administrative procedures apart from the technical procedures. As to just how this technical group is to be operated and financed, the answer is not clear as yet. However, it appears that we shall be able to work out the financing of this central blood bank or this blood donor service in cooperation with hospitals. Particularly our small hospitals need this service. I should like to have you know that we are alert to this opportunity for usefulness, and I have an idea that we are going to do it and we should like to have your help.

DR. W. L. BIERRING, Des Moines, Iowa: As the Iowa state commissioner of health, I should like to offer the following comments: In this blood bank program for peacetime I feel that there should be first a close cooperation between the Red Cross and the state health agency. In the distribution of the service that seems to be the logical state agency. I feel that at least in states of a certain size it is the logical function of the state department of health to process the blood plasma or other substitutes of whole blood for transfusion purposes for the entire state. Speaking from an experience of four or five years largely in the processing of pooled convalescent serum for scarlet fever, measles and whooping cough, and three years of experience in the processing of blood plasma, pooled blood serum and other substitutes and of distributing these units throughout the hospitals of the state, we have received the fullest cooperation on the part of hospitals as well as of all the local medical societies, and it is my feeling that that is a logical function of a state health department. We are requesting from the next legislature the building of a special laboratory building so that we shall be able to process blood plasma for the entire state, and it is our hope that we can cooperate fully with the Red Cross, because it is most valuable in the enrolment of donors, in carrying out various arrangements that are necessary and in providing the mobile collecting unit. We have the best type of facilities for processing pooled blood, collecting blood from hospitals and then processing it for them, possibly at cost price in some instances. It would be our thought that blood plasma or its substitute should be made available to every person in a community. If there are contributions from those who are economically able, that will help in maintaining the cost of the central unit. I should like, furthermore, to call attention to the rather remarkable way in which blood collection has been carried on by the Red Cross for war purposes: the arrangement of a suitable place for collection, having a courteous attendant who gets their names, having a physician present to make at least a general examination, listing the age of the donors and then serving them with coffee and sandwiches or some slight repast, giving them an opportunity to lie down for a half hour or an hour, and making them go away from the central station with the feeling that they have really done something, that they have contributed something to their country and in the future to their community. I feel that there is a psychologic side to this. You must have the cooperation of the donor. In certain instances in the past we have paid donors, but I think in the future that will not be necessary. However, I am sure that a coordinated program on a statewide basis in states of a certain size is the logical procedure to carry on. At least that is what we hope to do. I understand that Michigan is going to follow out the same plan.

DR. L. W. MASON, Denver: I am glad for this opportunity to say just a few words about a civilian blood bank which we have in Colorado. This bank was begun about two years ago, and it has been in operation for something over a year and a half with funds supplied by Helen Bonfils in memory of her mother, Belle Bonfils, who was the widow of the founder of the Denver Post. If there are persons in one's community with a considerable amount of money, I am sure that nothing would appeal to them more than to give money for the establishment of a civilian blood bank. The name of this bank is the Belle Bonfils Memorial Blood Bank. The technical work is done at the Medical School at the University of Colorado, in the department of clinical pathology. There is a full time technical director, Dr. Marion Rymer, who has charge of it. There was a little difficulty, of course, at first in getting a suitable number of donors to get it started. As far as I know it has not inter-

fered with the Red Cross blood bank for war purposes which we have there and which has always met its quotas without any difficulty. One interesting thing about this in particular that I thought might be of value to those of you who might be contemplating initiating such a project in your own community is the way in which the donor clientele has been built up. At first the plasma was kept at the medical school and dispensed from there. A little later, as the bank grew, plasma depots were established in all the private hospitals in Denver as well as in the county hospital. At present depots are established all over Colorado, so that there is no place in the state from which plasma cannot be obtained in a short time in an emergency. I think there is a tremendous need to continue this activity after the war is over. It isn't always possible immediately to get a donor and to get patients transfused with whole blood, in obstetric accidents, for example, or in industrial accidents, where there has been considerable use of whole blood and plasma. Now the interesting way in which the donor clientele has been built up in Colorado is this: Any doctor in the state is entitled to draw on the blood bank for whatever plasma he needs whether it is 250, 500 or 1,000 cc. or more. The one who gets the plasma is obligated to see that friends or relatives, three of them, report to the blood bank at some time in the future as donors. Of course, not all of them do that, but I presume that 90 per cent have done so. No charge whatever is made to any patient, whether he is indigent or a millionaire, for use of the plasma. The payment is in further donors of more blood or more plasma. That civilian bank has grown. It is entirely successful and, of course, it has been a godsend to doctors who need plasma in a hurry. All the private hospitals can get it at a moment's notice and it is now distributed over the state, so that these centers all over the state are within accessible distance to any doctor in Colorado.

DR. ROBERT McIVER, Jacksonville, Fla.: I should like to ask Dr. Robinson if at the present time the armed services will accept plasma from civilian blood banks. At one time they would not and I had some correspondence with Davis and a very nice letter from Dr. Robinson about it, but they were not able to accept the plasma from the bank, and that led us into this rather unfortunate situation that I believe could have been avoided had the armed forces accepted even a token amount of plasma from the civilian bank. When we were not able to tell people who were giving blood that we were sending it abroad a great many lost interest, even though we offered blood and plasma to the armed services in our vicinity and it was accepted. We processed blood, for instance, for the naval dispensary at the air base, technically phrased, in containers furnished by the Navy, and we had fine cooperation there. We had a lot of donors from the base and we sent a good deal of plasma out to the base and that worked out fine. I was interested in what the doctor from Colorado said about a fund or an endowment that would take care of the finances and we did not have to extract from the recipients of this service any fee. Our first fee was \$3 when we were financed by the Civilian Defense. They gave us about \$1,000 a month, and we made a token charge of \$3 to cover expendable material, not as a service fee at all. Now the Civilian Defense has withdrawn that support and the blood bank has become an independent institution and it is financing itself by a service charge of \$10. I believe that if the Red Cross would, in civilian life, bring up the donor problem and keep feeding it, it would be all right provided no charge was made for any of the service anywhere along the line. We use the same system that is used in Colorado. We give the blood out on the call of any doctor in any amount that he needs. We do not expect anything for it right then, but we hold the doctor responsible for the donor replacement. I am sorry to say that ours has not been anything like 90 per cent. Most of our doctors are in the red, and we have to keep on having revivals and talks to get them to spruce up and get the donors. In spite of the fact that some are deeply in the red, we continue to give them any and all of the blood or plasma that they need on call. All of it is deposited in all the hospitals. The bank is established as an independent institution not for profit, incorporated. It is self supporting. All of the personnel are full time, and all of the directors serve without pay and the plasma is kept in all the hospitals. We have a separate white and colored bank, being from the Deep South. The colored

hospitals have plasma on storage and the blood is sent on call. All of the work, from the typing to the delivery of the blood and plasma and the apparatus to give it, is the responsibility of the bank and it is all done at the bank.

DR. W. F. DONALDSON, Pittsburgh: Before the war, as a matter of fact through the Committee for the Control of Acute Appendicitis Mortality of our state medical society, we interested the health department of the state in the establishment of a mobile laboratory and visited all of the small hospitals in the state that would guarantee a certain number of donors to be on hand the day the mobile unit arrived. This blood was taken back to Philadelphia and processed and about 90 per cent of it returned to each hospital, probably 10 per cent being held in a common fund. It was then returned to the hospital, at a price of \$3.75 for each pint, with the understanding that no charge would be made for the use of that blood plasma.

DR. HOLMAN TAYLOR, Fort Worth, Texas: I see no reason in the world why the American Red Cross should not continue as a peacetime occupation its blood donor service, which it has done so successfully during the war, provided it continues its policy of cooperating rather than supplanting agencies that are working along that line. It occurs to me that the name of the Red Cross will go far toward getting blood donors where the use of various revivals in the interest of local enterprises might fail. In Texas there are two well established, relatively long established, blood banks, one conducted by the state health department in its excellent laboratories, and the other a private, nonprofit enterprise in the city of Dallas by Dr. Hill. Now if the Red Cross should go down there in Texas and cooperate with the state health department and cooperate with that blood bank in Dallas, it would be helping and they might need its services. They might not, but at any rate the cooperation wouldn't harm. But I think it would be a mistake to try to supplant that service. Dr. Hill's blood bank in Dallas is nonprofit, as I say. They make a charge of \$5, I believe, and a replacement of the blood when the blood is given for private use. That is to cover the overhead and, as the overhead is reduced, that charge is reduced also. The great open spaces in Texas cannot furnish that kind of service and therein lies the great opportunity of the Red Cross, and there is no reason I can see why we should not approve of the idea. The Red Cross must have work to do in the interim between wars in order to maintain at least a skeletonized organization, else it will not be ready when war comes.

DR. G. CANBY ROBINSON, Baltimore: Dr. Mason's account brings up the question Is the Red Cross needed or necessary to carry on blood banks on a state-community basis? Dr. McIver's question about the use of blood for the armed forces from other than Red Cross blood donor centers has been one that we have had to face many times, and it has been one of a good deal of embarrassment. We gather the blood and turn it into the laboratories. Now the question is May any other agency gather blood and turn it into the laboratories? I can say that it is illegal from this sense: The laboratories are licensed by the National Institute of Health of the Public Health Service. That license has a legal standing and that license extends into the procurement. Our centers are inspected by the laboratories and by the National Institute of Health to see that we are carrying out the whole technical procedure according to the specifications of the National Institute of Health and are fulfilling the licensing certificate. So that it is impossible for the laboratories to receive blood from private or other agencies for processing for the Army and the Navy to be shipped overseas. There have been several instances in which the local blood bank has fulfilled a need of a local military establishment, such as Dr. McIver has mentioned, but that is not quite the same as sending the blood into the whole great pool for processing. The Army and the Navy, as a matter of fact, have taken some steps to have blood and plasma available for these local establishments, so that they will not have to call on the local banks. I think, however, the local bank that has been in a position to give that service has rendered a great service. But it has not been possible for the Army and the Navy program to take blood in this processing and sending overseas except that which has been secured through the Red Cross blood donor service.

DR. G. FOARD MCGINNES, Washington, D. C.: The first program which the Red Cross chapters cooperated with was in 1936 in Augusta, Ga. That program received a great deal of national publicity. Following that, for the next few years, about ten Red Cross chapters participated in some type of blood procurement program. It was never extensive, but that program did lead to our present national program for the armed forces. Dr. Bierring mentioned the statewide program as he anticipated it in Iowa. I might say that Michigan already has a statewide program, which is carried on under the auspices of the state health department with an appropriation from the state legislature. The Red Cross is now cooperating with that program. We are the donor procurement agency throughout the state of Michigan and that program is going along nicely. We are familiar with the Pennsylvania program. It is a program that has been carried on by the state health department for a long time, in which it furnishes blood to the various hospitals throughout the state with a replacement program. We are familiar with the program now being carried on in Texas both by the state health department and by Dr. Hill in Dallas. The state health department has a good processing unit at present and is carrying on. It has requested the Red Cross to participate in the program and we have already through a few of our chapters, but more recently they have asked us to cooperate with them on a statewide basis. Several states, I think now something like six, have asked us to cooperate with them in peacetime, but we do not have a peacetime program so no answers have been given to them. In Iowa we are also cooperating through some of our local chapters with the state program. So we have had a permissible program for our chapters to participate in community and state programs during the war.

[NOTE.—By a show of hands those present unanimously approved participation by the Red Cross in a peacetime blood procurement program.]

THE PHYSICIAN'S ATTITUDE TOWARD THE EMERGENCY MATERNITY AND INFANT CARE (EMIC) PROGRAM

E. D. Plass, M.D., Iowa City

No single recent development has so disturbed our profession as has the inauguration and expansion of the federal government's program to provide medical care for the pregnant wives and young children of enlisted men of the lowest four grades. The ill advised placing of the project under the Children's Bureau and the regulatory measures devised by that group have given substance to the specter of "state medicine" and have alarmed the profession. Organized medical groups have almost without exception condemned the program but have cooperated from a sense of patriotic duty, a situation which may well have been envisioned by those who maneuvered the Congress into taking the actions it did and the profession into an intolerable dilemma. The result has been an unprecedented confusion of thought and emotion, which has led nowhere in particular. We have blamed the bureau when we should have put the responsibility on the Congress, we have fought against minor inconveniences and inequalities but largely ignored the fundamental issues and we have wasted our time on resolutions when resolute action offered the only chance for relief.

Many of us have failed to see the forest for the trees and have spent our energies criticizing the bureau for regulations actually demanded by the actions of the Congress under which the bureau operates. This is not to say that the bureau is blameless but rather to imply that the Congress should bear the major portion of the blame for playing deliberately into the hands of those in the official Washington family who admittedly want to socialize medical practice or for failing to recognize that the mandates it gave the bureau were too general and would lead to an onerous form of regimentation. There is little doubt that the bureau built up a small and local need to a near national catastrophe and sufficiently impressed a Congress which wanted naturally to do everything reasonable for our fighting men. The charge that the bureau had no statutory sanction for its incursion into the field of medical care is not strictly

true, since it was the agency to which the funds for the program were allocated by the appropriations, but the history of the bureau does show that such a function was never proposed until the present "emergency" arose. The act creating the bureau, passed on April 9, 1912, limits its functions to investigating and publishing the results of investigations on a variety of factors affecting children, among which "questions of infant mortality," "the birth rate" and "accidents and diseases of children" alone have direct medical implications. The assistant chief of the bureau has implied that the Social Security Act of 1935 considerably extended the scope of the bureau's recognized functions, but this legislation appears only to provide for "the development of demonstration services in needy areas and among groups in special need."

It seems clear that the bureau has for the past eight or ten years, at least, been making efforts to enter the field of medical care. In 1936, soon after passage of the Social Security Act, a few "demonstration areas" were organized, wherein physicians were paid for providing antepartum care and public health nurses were employed to assist the physicians in the care of mothers and children. Evidently the original small EMIC project in the Pacific Northwest was designated a "demonstration" and as such not inconsistent with the established statutory functions of the bureau. Some observers wonder whether the "foot in the door" was placed there under strictly humanitarian motives or whether it was the opening that had been awaited for years and which had to be exploited quickly. Subsequent events suggest the latter, and it was cleverly done.

Slightly more than three years ago the commandant at Fort Lewis requested the Washington State Health Department to assist in obtaining maternity care for the wives of enlisted men at that post, since the facilities of the station hospital had become inadequate and the county hospitals could not admit non-residents. The health department soon exhausted its available funds and appealed to the Children's Bureau, which met the emergency from unexpended sums in its budget. It should be noted that the program was started on the basis of need, while now the bureau is stressing the point that no "means test" can be applied. "Need" was essential for establishing a "demonstration area"; but with the program expanded to the four corners of the country there was no need for "need." The service was widely publicized in the public press and has been advertised through special notices distributed with allotment checks. The latest such leaflet reads "If your husband is in the 4th, 5th, 6th or 7th grade (the lowest four enlisted grades) of the Army, Navy, Marine Corps or Coast Guard, or if he is an aviation cadet, you are entitled to medical, nursing and hospital care, where it is available, throughout your pregnancy, at childbirth and for six weeks after." "The care will cost you or your husband nothing. No questions are asked about your income."

The initial deficiency appropriation measure specifically authorizing the Children's Bureau to undertake the emergency maternity and infant care program made such assistance available only when "similar care was not available from the medical and hospital facilities of the Army and/or Navy. . . ." The bureau, even in its early interpretative publications, changed this to read "Similar service is not readily available (without financial investigation and without cost) from the medical personnel or hospitals of the United States Army, Navy, Public Health Service or from clinics or conferences or other services provided by or through state or local public health agencies. . . ." That policy has the earmarks of an emergency setup until it is realized that all charitable state and local medical services and hospitals demand a "means test" and that the availability of services in governmental hospitals is determined by the commanding officers. For the past two or three years many city, county and state general hospitals have been operating far under capacity, as is usually true in periods of full employment and high wages. And yet these facilities and the medical personnel to operate them cannot be used to full advantage in meeting the "emergency" because of the bureau's insistence that no "means test" be applied. On the other hand, some private hospitals are being seriously inconvenienced by the demands of the wives of service men, who want care under the EMIC program and insist on the full fourteen days hospitalization offered them by its provisions. The philosophy involved in the

contention that a gift of medical and hospital attention is not "charity" if the funds derive from the federal treasury but is "charity" when financed by local or state taxes is consistent only with the other inconsistencies the bureau has thrown around the program for reasons best known to itself.

These developments indicative of the evident desire of the bureau's officials to participate in medical care on a large scale should be considered in light of the Report of the Interdepartmental Committee to Coordinate Health and Welfare Activities under the chairmanship of Josephine Roche, released on Jan. 23, 1939. This document contains the following pertinent statement: "The most serious deficiency in the present maternal and child health program is lack of provision for medical care for mothers and children who are so situated that they cannot obtain needed care without some form of assistance from the community." The Children's Bureau was represented on the committee, and the statement quoted surely would not have been included without their approval, and there is some reason for believing that it may have been included at their request. It appears likely that the bureau officials wanted to get their hands on medical practice, and it can at least be surmised that the "shoestring" relief affair developed in the state of Washington was expanded purposely so that the bureau would have a valid reason for appealing to the Congress for additional funds to be placed with the bureau for administration. At least, such an inference suggests why, early in 1942, several states were advised that they could have \$10,000 each, out of available funds amounting to \$198,000, for emergency care of the wives and children of service men who could not obtain such care because of nonresidency. In some states this offer was made at a time when it was not realized by the authorities that the states had such a problem. There is, of course, no good way of proving that these suspicions are entirely correct, but certainly the factual data advanced suggest that they are not too far wrong. Increasing sums were allotted to the various states on the basis of their probable needs for carrying out programs which they developed but which had to be cast in similar molds in order to win the approval of the chief of the Children's Bureau. The regulations developed by the bureau for the guidance of the various state health agencies had a certain elasticity in everything except the fundamental social philosophies involved. Experience with the functioning of the program has resulted in modification of many of its regulations, but not with the basic principles that especially concern the profession. It is this regimentation which has produced and stimulated the friction between the bureau and the majority of organized medical groups.

The most controversial issue is the method of payment, which, under the regulations, is made by the health agency directly to the physician, thus violating the supposedly sacred right of the medical man to make his own financial arrangements with his patients. Collectively, we object to this intervention of a third party, whoever it may be. The blame for this situation lies directly with the Congress, and the bureau is obviously carrying out a congressional mandate when it insists on direct payment. The record seems to indicate that the Congress had heard harrowing tales of men returning from World War I to find themselves deeply in debt for medical services rendered to their families while they were fighting our enemies. Undoubtedly there were also debts for other and less necessary things, but all the emphasis was placed on unpaid professional service and hospital bills; since they were seemingly unavoidable. A palpable flaw in this line of reasoning is apparent when it is remembered that the government is concerned only with bills for services rendered the enlisted man's wife while she is pregnant or within six weeks after delivery, and for the first year of his child's life. No provision is made for other and more catastrophic illness occurring outside these narrow limits. The Congress is said to have had in mind "the effect the assurance of such care would have on the morale and peace of mind of the enlisted man himself." Surely, debts for maternity and infant care cannot be the only ones which haunt the mind of the man overseas—they are no different from other debts; at least the accoucheur generally has no smaller percentage of uncollectable bills than practitioners in other lines. The whole thing suggests that the political aspects of the problem, and they are admittedly great, must have been given undue weight.

In any event, it can be safely assumed that our legislators were in no way solicitous for the obstetricians.

The second moot point involves the regimentation of these pregnant wives and young children of service men into one absolutely delimited class. They must obtain professional care and hospital service of a uniform financial pattern. They cannot rightfully pay any additional sum to the hospital in order to secure better accommodations than the ward service which is prescribed in the regulations nor can they pay, or the physician accept, more than the standard maximum fee for professional services. Moreover, the wife cannot accept professional care for herself or her child in a hospital without accepting such institutional care, or vice versa. It is an all or none proposition. The philosophy of such a regulation evidently stems from and is perhaps reasonably deduced from the action of Congress in demanding that payment be made directly to the physician and the hospital. That body wanted to protect the returning veteran from bills for medical services and hospital care contracted by his wife for luxury attention but was unconcerned about other extravagances which might well lead to even greater debt accumulations. Again the Congress appears to bear the responsibility for bringing about a situation which is irksome both to the profession and to the patient. The only answer that has been forthcoming is that the enlisted man's wife and child are under no obligation to request care under the program; if they do not like the provisions made available for them they are free to make their own arrangements, but by doing so they forfeit all claim for governmental assistance.

The third serious situation developed by the program is the scrapping of more than a decade of work by the bureau in developing standards for physicians who participate in such governmental projects. Previous smaller programs had limited participation to graduates of recognized medical schools. Even though such limitations may not have had statutory backing they had been made to stick, and attempts on the part of the irregulars to void them had been unsuccessful. Apparently, under congressional pressure of the cults the states have been compelled to accept requests from, and to make payments to, any one recognized as capable of giving obstetric care under their individual statutes. The Congress must likewise assume the responsibility for this threat to the quality of medical care and bear the burden for having discriminated against the wives and infant children of service men. Persistent efforts to obtain the passage of legislation making cultists eligible for the army and navy medical corps have resulted in failure, apparently because the legislators recognize the deficiencies of their training; but these same irregulars are fit to treat the wives and children. The Congress must take the blame. The one hope is that this program will end with the war emergency, as has been promised by several of those concerned with its administration, and that the old standards can not only be reestablished but even made more rigorous.

Up to this point it might seem that the bureau is not responsible for those fundamental concepts which have so aroused the profession, and it may be; but the possibility always remains that the administrative officials of the bureau influenced the Congress directly or through committee members to write the legislation as it was passed.

Until recent years the bureau had held to investigations and reports and to sponsoring and financing postgraduate courses in obstetrics and pediatrics and in so doing had gained the support and approval of the profession. The task set it under the public statutes would seem large enough to have occupied its personnel, but those in charge evidently saw in the situation created by the war a chance to experiment with medical practice under the guise of an emergency. Incidentally, the purposes outlined in its creating act have evidently been shelved and certain projects in those areas, such as the investigation of eclampsia, have been dropped in order that the office may devote its entire time and energy to implementing certain plans for regimenting the medical profession and a good portion of its maternity and pediatric clientele. And the assistant chief of the bureau has not hesitated to say in public that the experience gained in this experiment will be useful in the postwar years, while on another occasion she denied any thought of continuing the program after the war emergency has passed into history. The gradual inching of the bureau into the realm of medical care

and the inconsistencies of the public statements emanating from its higher officials, which are matters of historical fact, have been important factors in making the profession distrust the intentions of those in charge.

And this distrust is behind much of the professional opposition to the present EMIC program—the "emergency" did not ring true, the regimentative regulations have not struck a true democratic chord, and the bureau's insistence on the maintenance of those administrative principles which violate traditional medical philosophies have made many of its former friends fear that it may have had more than a passive role in determining the disruptive acts of Congress, which lie at the base of the disharmony existing between the bureau and the medical profession.

Physicians, individually and collectively, have always agreed that the wives and children of our fighting men should be adequately cared for, and that this care should extend not only to the period of pregnancy and six weeks after delivery or to the first year of life, as provided by the EMIC program, but even to the nonpregnant state and to children more than 1 year of age. No evidence has yet been adduced to show that the latter women and children have been neglected by the profession merely because no federal agency will pay the bills. In any one calendar year it is safe to say that not more than 10 per cent of the wives and children of enlisted men in the specified grades qualify for this attention. What happens to the other 90 per cent? Every one seems to have overlooked them and the fact that they may be ill. It would not be popular to tell this audience that they are being medically neglected—and it would not be true.

The more discussed but less important objections to the bureau's regulations concern chiefly such things as payment on a cash basis without regard for the complexity and duration of the medical problems involved, the uniformity of payment irrespective of the professional status or the overhead of the physician, the complexity of the required forms, the legal hazard in the approved contract form, the failure to make well baby care available and similar minutiae which have some present importance but no far reaching effects on the practice of medicine. The maximum fee of \$50 for complete obstetric care possibly tends to set a countrywide financial standard that will work a hardship on practitioners in the larger communities where operating overhead may exceed that figure, but on the other hand it definitely raises the fee in most small communities and in rural districts to a point which staggers the imagination of the physician who has done obstetrics all his life for \$15 to \$25. But even here the harassed practitioner is under no compulsion to accept the responsibilities for the care of wives of nonservice men for less than his regular figure. Fear of the charge of lack of patriotism, which has been such a potent lever in forcing the extension of the EMIC program, does not here enter the picture. Moreover, recent amendments to the regulations have met many of the aforementioned trivial objections by increasing the financial remuneration under certain specified conditions, a time honored and effective political maneuver, anticipated by those familiar with the bureau's machinations.

The bureau evidently has taken the attitude that it is wise to make minor financial concessions to pacify the majority of medical men, who think more of the present than of the future and who largely ignore the seriousness of those objections which were discussed earlier. Its officials insist that the bureau is merely following the congressional mandate in maintaining those concepts which have drawn the fire of organized medicine. It also seems clear that they will fight for their retention because they feel that this nation should have a federal health program which in the terms of the Interdepartmental Committee's report would provide both for the "self supporting" and for the "needy," and that the EMIC program is a proper experimental step in that direction.

Obviously, then, we should no longer waste our time and energy in representations to the bureau but should go to that higher authority, the Congress, from which the bureau obtains its power and funds. It is only from that body that we can hope for any relief, and many feel that that hope is very slight at best. It cannot be denied that sentiment for compulsory federalized health insurance is strong among our legislators

and that powerful political groups are applying pressure to have the next Congress consider the Murray-Wagner-Dingell bill, or some such inclusive proposal. If perchance the new legislature should veer away from the advanced social trends that are now dominating the thoughts of the powers in Washington, the time should be ripe for an attack on bureaucratic controls and for repeal of those provisions of the present statutes which made the physicians the pawns of governmental agencies.

Finally, the split personality of the medical profession must be introduced as a factor which may well decide the issue. Many thoughtful observers, even within the profession, see the quest of the almighty dollar, as expressed in unnecessary operations, needlessly prolonged and expensive treatments and costly diagnostic procedures as the basis for the current demand for a comprehensive national health service. The same monetary urge has made the physician oppose the EMIC program violently in his society meetings, even while he is accepting as many patients as come to him for care under its provisions. Unless and until we, as individuals and as groups, can decide whether we want freedom or domination, professional independence or official regimentation and develop a conviction which carries to our offices as well as to our society meetings, we cannot expect to wield the political force of which we are capable. And let us not forget that this is a political game and that the cards are being stacked against us even by our own activities. The bureau is under the control and direction of experienced and adroit politicians who are adept at exploiting divisions of opinion among its opponents. The personality rift that separates the physician in his office from the same individual in his society meetings offers the type of situation the politician desires. He assumes, and apparently quite correctly, that if he pacifies the former by increasing his fees he may largely ignore the other. The fact that the EMIC program is working so satisfactorily converts our arguments that socialized medicine is inefficient and far below the standards set under private initiative. Moreover, let us keep in mind that 11,000,000 of our men are receiving better medical care, curative and preventive, than they have been accustomed to as civilians.

If now we still feel that we do not want any part of it, let us be realistic; let us unite and present our appeals for relief to the only group that can provide it, the Congress. Let each state or each group of states send its representatives to Washington to inform our representatives of our objections, and let us make those requests similar enough so that there can be no mistake about our desires. It is only in this way that we can hope to retain or to regain the national reputation and prestige the profession has so long enjoyed by reason of its humanitarian ambitions. By opposing the present program and its logical sequel, a national health service act, without offering another plan which will resolve the admitted inequalities of the present system of medical practice, we brand ourselves as nonprogressive reactionaries and still further lower ourselves in the eyes of the public. If we cannot unite in opposition to the present efforts to regiment the profession, let us continue to make the EMIC program work, and then let us cooperate with the national administration in setting up a health insurance program of which we and the country can be proud.

DISCUSSION

DR. THURMAN B. RICE, Indianapolis: I want to present this subject from the point of view of practical administration. It is impossible for me to know just exactly what the intention of the people in the Children's Bureau was. Dr. Plass believes that they were definitely politically minded and that they were deliberately setting up something here that would enable them to get hold of the whole situation. If it is true, it is a serious indictment. My own feeling is that they did not intend it that way quite as strongly as Dr. Plass implied. I believe that they are leftist inclined. I believe that they honestly believe in the sort of thing that they are doing. I believe that they saw in this an opportunity to usurp a function which Congress did not give them as I read the act. When they got into it, it was much bigger than they realized. There is a disposition at the present time for them to modify it here and there, without, as Dr. Plass pointed out, modifying the basic fact where the basic error was committed. According to the law they are to give infant care "under allotments by the Secretary of Labor and

plans developed and administered by state health agencies and approved by the chief of the Children's Bureau." It would seem that the plans were to have originated in the states and to be administered in the states and that the approval of the Children's Bureau is something that comes after. I do not believe that Congress intended that the Children's Bureau should lay down plans covering every state in the Union and also covering Puerto Rico, the Hawaiian Islands, Alaska and the Virgin Islands. Congress said here that the state makes the plans and administers them and that the Children's Bureau approves them. This came on us so suddenly and it is such a large administrative problem that it simply overwhelms us. Actually more than half of our budget is this money. It takes a vast amount of clerical and bookkeeping work to get this stuff through. We have asked for decisions. Three or four months later we would get a letter perhaps telling what we should do. In the meantime the woman has delivered the baby. Then you try to go back but you can go back just about as easily as the woman can go back on that physical process. Sometimes we have had physicians operating under as many as three sets of price schedules. For example, a woman is reported pregnant, we will say, in May, and she is taken and the funds are encumbered. A little later another woman comes in, in June, and in the meantime the rules have changed. Well, the funds must be encumbered, as the rules say, at that time. Another woman might come in in September and there is still another set of rules. That physician must charge and send in his bill according to the particular set of rules that were in force when the woman first came to him. So he will deliver three women in one week on three different fee schedules. The Children's Bureau in times past has done a pretty good job teaching the profession about good obstetric care and pediatric care. I seem to remember that they have taught us that the woman ought to go to the doctor once a month as soon as she finds that she is pregnant. During the first five months that would be four visits. Then for the next three months she ought to go twice a month. That makes ten visits, and the last month, the ninth month, she ought to go once a week and that makes fourteen visits. How much do we allow for the antepartum care? Ten dollars. How much a call do we allow for antepartum visits? Two dollars. That is some high falutin' arithmetic: fourteen times \$2 equals \$10! They have taught us good antepartum care but when it comes to paying for it they are afraid to trust physicians. They are also afraid to trust health administrators, and they are also afraid to trust the soldier and his wife because they won't give her the money. That is teaching distrust in a big way and it is confusing. The Children's Bureau has permitted blame for difficulties to fall on the health departments and on the doctors, but not on itself. One tremendous benefit has come out of this. It has sometimes helped the woman, of course, but there has been another enormous benefit. This is a guinea pig which is of great value in showing us what kind of a mess we would be in if we had the whole program. For the present current year the program in the whole United States amounts to \$42,800,000. The whole Wagner-Murray-Dingell program I have heard estimated all the way from 3 billion dollars to 12 billion dollars. I do not know which is right, but if we have this much trouble administering \$42,000,000 we would certainly be in a mess if we had to administer 3 thousand million or 12 thousand million dollars.

DR. GEORGE H. KRESS, San Francisco: I cannot agree with the statement that Congress is to blame for enacting an EMIC program that contains provisions to which physicians object. We should blame ourselves. Organized medicine was not alert when the program was brought into being by the Federal Children's Bureau. Up to October 18 last, New York had 47,000 EMIC cases. California was second with 34,000. Dr. William B. Thompson of Los Angeles, a member of the California Medical Association Committee, was called to Washington to give testimony before a congressional committee. Dr. Bierman of the California Maternal and Child Welfare Bureau submitted for our California committee some requests to the federal Children's Bureau in the hope of rectifying some of the deficiencies in the federal bureau's procedures. Our suggestions had to do with payments to physicians in sparsely settled areas in which certified specialists were not available and for compensation to

physicians in such sections who were obliged to use their own x-ray and other equipment. A simpler form contract was set up for California, and some dangerous provisions that had malpractice implications were deleted. When Dr. Daily first came to California with the federal Children's Bureau he stated that \$35 should be the total compensation. California insisted that at least \$50 be paid by the government for each EMIC case. That fee has now been established in practically all states in the Union.

DR. H. H. SKINNER, Yakima, Wash.: It is in my state that this program was initiated, and it was my questionable privilege to have been chairman of the committee that started this. The problems before the medical profession and the United States at present is free medicine. The EMIC program is the proposition which appeals to both the United States and the profession as being the entering wedge for that very proposition. The Miller bill has not been mentioned yet this afternoon and it may not be, but I wish to go on record as favoring it. If we are going to get anywhere we must do something. We can do it only through Congress. Some of you know Congressmen. It has been my privilege to talk to a number of Congressmen and they are unified on this one point: they do not know what is going on in the medical profession. We have not told them, but they are willing to listen. Are you willing to spend some money for it? The chiropractors are willing to spend \$200 apiece a year. Would you be willing to spend \$10, \$15 or \$25 and put yourselves in a class with the chiropractors by spending some money to send a man to Washington to confer with your congressional representatives, merely stating how you feel in your community through your state organization? Iowa has been doing it. Let us go to our representatives in Congress, but we must have one concept.

DR. L. J. MOORMAN, Oklahoma City: When this proposition first came to the state of Oklahoma, our commissioner of health, who is a good doctor, loyal to hippocratic principles, was troubled about it and called for a committee. As a member of the committee I opposed its acceptance unless under coercion, because I figured that doctors might go on doing obstetrics as they have always done, for something or for nothing, and I figured that any doctor's personal liberty is at any time worth more than an obstetric fee. However, we did put the plan into practice, and I am gratified to see how many of the doctors feel about it here today. I want to say this one word, which covers this proposition and our present situation: We have been so busy keeping up with the science of medicine that we have neglected the art of medicine to the point of losing much of our highest rating in the minds of the people. While we have been busy following the science of medicine, some of our representatives in Washington have been busy for twelve years depreciating the standing of medicine with a propaganda which has covered the whole country. We have lost our opportunity to a great extent. If we recover our position it must be through education of the people, the patient and the patient's friends. The most good will be through the doctor's personality impressed on his patient.

DR. E. D. PLASS, Iowa City: There seems to be unanimity of feeling that the program is wrong and that the only method of attack is through Congress, but I should like to say just a few words in justification possibly of the Advisory Committee. It is exactly what its name says. It has absolutely no power. All it can do is go before the Children's Bureau and offer its ideas, which the Children's Bureau then accepts or flauts as it chooses. It should perhaps also be emphasized that, when this program was first inaugurated and when the first regulations were sent out to the states, the Advisory Committee was called in for a meeting after the regulations had gone to the states, and we were then told "We would like for you to discuss the various features of these regulations, but we want no motions." That is the authority of the Advisory Committee, and I think perhaps you should not be too critical of the committee.

DR. THURMAN B. RICE, Indianapolis: I actually believe that if every one who is interested in this would talk to or write to his Congressman there would be some result and that the Children's Bureau would have to listen and it would be less autocratic than it has been.

(To be continued)

Washington Letter

(From a Special Correspondent)

Jan. 8, 1945.

UNRRA Has Important Role in European Health

Herbert H. Lehman, director general of the United Nations Relief and Rehabilitation Administration, has reported after a six weeks trip to London and the continent that "the chief responsibilities of UNRRA in the paying countries of western Europe for assistance to the military are in the fields of health, welfare and displaced persons operations." In occupied Germany UNRRA will work with displaced persons under direction of the military. Mr. Lehman disclosed that UNRRA is ready to send relief supplies to Poland and Czechoslovakia if Russia will receive and distribute them. In London he concluded agreements with the governments of all the western European United Nations—Norway, Belgium, the Netherlands, France and Luxembourg—for the dispatch of UNRRA liaison missions to them, to deal chiefly with health, welfare and displaced persons aspects of relief problems. UNRRA has accepted the invitation of the Czech government to send a representative with a group of Czech health experts to liberated parts of that country. Medical supplies will be an important part of first relief shipments to Czechoslovakia. Mr. Lehman said it was hoped that relief imports would be financed by the individual governments able to do so, thus making more of UNRRA's limited goods available to governments lacking foreign exchange resources.

"Luxury" Private Nursing Demands Criticized

Hospital officials called together by the Nursing Council for War Services have criticized the continued demand for "luxury" private duty nursing, with the Army and Navy in urgent need of 14,000 additional nurses. A public meeting planned by the Graduate Nurses' Association for January will emphasize the drastic shortage of nurses for the armed forces and at the same time honor nurses with overseas service. The need for nurses is so acute that Congress may be asked to investigate the shortage, which has resulted in eleven general hospitals being sent abroad during December with no nurses in their personnel. Congressmen back from overseas were indignant that sufficient nurses are not available to care for the wounded. They have made the charges (1) that civilian hospitals are "hoarding" nurses and (2) that superintendents and other hospital officials are threatening nurses that if they join the armed forces they will not be allowed to rejoin the hospital on their return to civilian life.

Capital Medical Center to Be Pushed

Erection of a mammoth government financed medical center in the Capital will continue to be sought, Senator Theodore G. Bilbo of Mississippi, chairman of the Senate District Committee, announces. Although additions have been authorized to Georgetown and George Washington hospitals here, Senator Bilbo said that he would ask the incoming session of Congress for action on the proposed medical center. He contends that it is needed despite the additions to existing institutions.

Charles F. Kettering Succeeds Dr. Anton J. Carlson

Charles F. Kettering was elected president of the American Association for the Advancement of Science, succeeding Dr. Anton J. Carlson, University of Chicago physiologist. Among vice presidents named were Dr. Warfield Longcope, Johns Hopkins, medical science; Dr. F. D. Kern, Pennsylvania State College, zoology; Dr. A. I. Hallowell, Northwestern, anthropology; Dr. Florence L. Goodenough, University of Minnesota, psychology, and Dr. Henry Eyring, Princeton, chemistry.

Reassuring Report Made on Army Hospitals

The House Military Affairs Committee has reported "reassuring" results in its long investigation of army hospitals. The War Department, the committee said, had taken corrective action in almost all suggestions based on its survey of eighty-nine hospitals in twenty states and the District of Columbia. There were twenty-eight specific cases listed without naming hospitals. Buildings in general were reported to be receiving proper care, although some had uncovered pin floors and needed paint and connecting passageways between

wards and main buildings. Fire equipment was said to be generally adequate, although one nonfireproof building dating "back to the Civil War" had bedridden patients on the second and third floors. One convalescent hospital used storage eggs which had not been inspected for nine months. They were served with catsup "to disguise their evil taste." Several hospitals were closed or not used to maximum capacity "despite overcrowded conditions elsewhere."

Representative Dingell Reintroduces Compulsory Sickness Insurance Bill

The 79th Congress convened January 3 and on that day Congressman Dingell, Michigan, reintroduced the Wagner-Murray-Dingell bill as H. R. 395. It was referred to the House Committee on Ways and Means. The Senate version of the bill has not as yet been introduced, but the medical provisions of H. R. 395 are identical with those contained in the legislation that was before the 78th Congress.

Postwar Medical Service

The Committee on Postwar Medical Service was called to order by the Secretary pro tem, Dr. Ernest E. Irons, Dec. 9, 1944 in the Board of Trustees Room of the American Medical Association building in Chicago. There were present Drs. Irvin Abell; Arthur W. Allen and Walter L. Bierring; Mr. Graham L. Davis; Capt. William E. Eaton; Drs. Evarts A. Graham, E. L. Henderson and Ernest E. Irons; Lieut. Col. Harold C. Lueth; Dr. Walter W. Palmer; Brig. Gen. Fred W. Rankin; Rev. A. M. Schwitalla, S.J.; Drs. H. H. Shoulders and LeRoy H. Sloan; Miss Mary Switzer and Drs. Olin West and Fred C. Zapffe, members of the Committee, and Dr. F. H. Arestad of the Council on Medical Education and Hospitals, American Medical Association; Lieut. Col. Gerard R. Gessner, Office of the Surgeon General, U. S. Army; Dr. Edwin P. Jordan, Assistant Editor of THE JOURNAL; Col. Hugo Mella, Veterans Administration; Col. George M. Powell, Office of the Surgeon General, U. S. Army, and Dr. R. C. Williams, U. S. Public Health Service, representing the organizations indicated.

COMMITTEE MEMBERSHIP

The Secretary pro tem announced the resignation of Dr. Roger I. Lee of Boston as chairman and as a member of the Committee on Postwar Medical Service because of greatly increased pressure of other duties. Dr. Lee's resignation was accepted with regret, on motion of Dr. Arthur W. Allen, duly seconded and carried. The Secretary pro tem informed the Committee that Dr. E. L. Henderson of Louisville, Ky., a member of the Board of Trustees of the American Medical Association, had been appointed by the Board to take the place of Dr. Lee as a member of the Committee.

Dr. Ernest E. Irons was elected chairman of the Committee. Dr. Arthur W. Allen of Boston was elected vice chairman.

The Chairman announced that Dr. Alan Gregg, a member of the Committee representing the American Medical Association, had resigned. The Chairman also informed the Committee that Dr. LeRoy H. Sloan of Chicago had been appointed by the American College of Physicians to represent that organization as a member of the Committee on Postwar Medical Service to succeed Dr. William B. Breed, deceased. It was announced by the Chairman that Dr. Willard C. Rappleye had resigned his membership on the Committee, that the Association of American Medical Colleges had been requested to name a representative of that organization to serve as a member of the Committee, and that Dr. Fred C. Zapffe of Chicago had been so named.

Dr. H. H. Shoulders, Nashville, Tenn., was elected secretary of the Committee, succeeding Dr. Alan Gregg.

REPORT OF SUBCOMMITTEE ON RELATION OF COMMITTEE ON POSTWAR MEDICAL SERVICE AND THE PROCUREMENT AND ASSIGNMENT SERVICE

The report of the Subcommittee on Relation of Committee on Postwar Medical Service and the Procurement and Assignment Service was read by Lieut. Col. Harold C. Lueth and,

after extended discussion participated in by Dr. Palmer, Miss Switzer, Lieutenant Colonel Lueth, Dr. Irons and Father Schwitalla, the report was accepted on motion of Dr. Palmer, duly seconded and carried, and the Subcommittee continued. The report was as follows:

1. This subcommittee was appointed by the Chairman of the Committee on Postwar Medical Service to draw up a statement of the relation of the Committee and the Procurement and Assignment Service.

2. In a recently published statement, the Directing Board of the Procurement and Assignment Service stated that, "as a war agency, this service is discharging and will continue to discharge its obligations until the end of the war. It will cooperate with the agencies concerned with the effective utilization of the individual members of these professions who are demobilized before the end of the war."

3. The Directing Board of the Procurement and Assignment Service regards their equipment and data as property of the United States government.

4. The present organization of the Procurement and Assignment Service in states and counties has had experience in advising with respect to local needs of doctors and the distribution of medical care. The people in the field organization of the Procurement and Assignment Service can in many instances, as individuals, provide valuable information in the future.

5. The Committee desires to retain the active interest of physician members of the Procurement and Assignment Service during the transition period and later when the Procurement and Assignment Service has ceased to function.

6. The cooperation of physician members of state and county organizations of the Procurement and Assignment Service will be of great assistance to the Bureau of Information of the American Medical Association and to the Committee on Postwar Medical Service.

ERNEST E. IRONS, Chairman.
HAROLD S. DIEHL.
MORRIS FISHBEIN.
VICTOR JOHNSON.
HAROLD C. LUETH.

FURTHER REPORT ON QUESTIONNAIRES SENT TO MEDICAL OFFICERS

Lieutenant Colonel Lueth reported that over 21,000 questionnaires had been returned and that in about two weeks 20,000 of the returned questionnaires will have been completed on the punch card system and minute analyses will then be made.

Lieutenant Colonel Lueth informed the Committee regarding a recent conference between Dr. T. C. Routley, secretary of the Canadian Medical Association, Dr. West and himself and stated that he expects to meet in the near future with Dr. Routley and Colonel Ledbetter of Canada. There was considerable discussion concerning what is now being done in Canada for medical officers back from active service for a period of home duty. A preceptor arrangement, whereby a returned medical officer is sent to a medical school and assigned to a specific man as his preceptor, seems to be the most promising idea that has yet been evolved. It seemed to be the consensus that the preceptor system would be difficult to operate successfully in this country because of the vastly larger number of persons involved.

REPORT ON QUESTIONNAIRES SENT TO HOSPITALS WITH REGARD TO AVAILABLE RESIDENCIES AND OTHER EDUCATIONAL OPPORTUNITIES

Dr. F. H. Arestad reported that questionnaires had been prepared by the staff of the Council with the aid of Lieutenant Colonel Lueth and had been sent to 1,050 civilian hospitals, approved for intern and residency training; that, for the purpose of information, the same material had been sent to the deans of recognized medical schools, to the secretaries of the constituent state medical associations, to national medical organizations, to the specialty boards, to the sections of the Scientific Assembly of the American Medical Association, to the editors of all state medical journals and to other interested

agencies and individuals, and that to date there had been a 20 per cent return. Dr. Arestad gave a summary of the results so far obtained from this questionnaire. He stated that all institutions, deans of medical schools and medical organizations from whom replies had been received indicated a sincere desire to cooperate fully with the Committee on Postwar Medical Service.

It was brought out that both the Army and the Navy were trying to develop refresher courses for returning medical officers but that these courses could be given only to men still in uniform.

Dr. Zapffe stated that the Association of American Medical Colleges was collecting lists of faculty members now in service whom the medical schools considered essential to the satisfactory operation of the schools. This matter was discussed by Dr. Palmer, Father Schwitalla, Colonel Powell and Miss Switzer, who stated that up to now the Procurement and Assignment Service has been handling demobilization of returned medical officers; that it helps to get facts together and advises on cases; that the Procurement and Assignment Service is looked to for information on communities in need of physicians, and that it would be glad to continue to do all this while the service exists. It was agreed by the Committee, on motion of Dr. Palmer, seconded by Lieutenant Colonel Gessner and carried, that the Procurement and Assignment Service is the logical body to handle this matter.

BUREAU OF INFORMATION OF THE AMERICAN MEDICAL ASSOCIATION

Dr. West informed the Committee regarding the organization of the Bureau of Information and called on Lieutenant Colonel Lueth, who has been instrumental in getting the Bureau started, to give a summary of its activities to date. (See THE JOURNAL, January 6, page 33.)

REPORT ON PROGRESS IN PLANS FOR DISPOSAL OF ARMY MEDICAL SURPLUSES

Miss Switzer reported that a Surplus Property Board has now been appointed and is awaiting confirmation; that it is not known whether the organization will be on a federal or a state basis; that the Public Health Service is now trying to formulate plans for the best way to distribute surplus medical supplies to places that need them, and that it ought to be known by the time of the next meeting of the Committee on Postwar Medical Service what the general lines of the surplus property distribution will be.

REPORT OF PROGRESS IN ARMY AND NAVY PLANS FOR RESIDENCES, GRADUATE STUDY AND REFRESHER COURSES FOR MEDICAL OFFICERS IN SERVICE

Colonel Powell stated that a committee had been established in the Office of the Surgeon General of the Army but that there was not yet any crystallization of ideas beyond what had already been mentioned at this meeting.

Captain Eaton stated that the Office of the Surgeon General of the Navy had a committee that had set up a proposed plan to bring back men from overseas and put them into hospitals where they could get further professional work. Captain Eaton described the Navy setup in detail and, during his remarks, said that the Navy hoped that civilian medical associations and authorities, particularly the specialty boards, would give naval medical officers credit for refresher courses the Navy has given them.

REPORT ON PROPOSED LAWS CONCERNING TEMPORARY LICENSURE

Dr. Walter L. Bierring, secretary of the Federation of State Medical Boards, was called on by the Chairman to inform the Committee concerning the status of laws that have been proposed or enacted to provide for the issuance of temporary licenses. Dr. Bierring stated that the resolution which had been adopted by the Committee at its meeting held in New York on September 9 apparently had met with some criticism, largely through misunderstanding, that the intent of the Committee was to facilitate the temporary relocation of returning medical

officers and that any action would be determined by local state needs and wishes. Dr. Bierring moved that the resolution previously adopted be restated. The motion was duly seconded and carried after discussion by Drs. West and Shoulders, Miss Switzer and Dr. Bierring.

The following resolution was drawn up by Dr. Bierring and Dr. Shoulders and was adopted by the Committee on Postwar Medical Service on motion of Dr. Bierring, seconded by Dr. Palmer and carried:

WHEREAS, Logical objections have been interposed by certain member boards of the Federation of State Medical Boards of the United States to the resolution adopted by the Committee at its meeting in New York City, Sept. 9, 1944, giving its approval to legislation proposed by the Procurement and Assignment Service, the Council of State Government and the U. S. Department of Justice, under which temporary licensure may be granted without examination to honorably discharged medical officers of the U. S. Army, Navy and Public Health Service and to physicians "who have rendered medical service during the period 1940 to 1945 in industry or in a civilian community"; therefore be it

Resolved, That the Committee restate its position as follows: That the Committee on Postwar Medical Service approves this legislation as far as it applies to the granting of temporary licensure without examination to honorably discharged medical officers of the U. S. Army, Navy and Public Health Service under the limitations and restrictions contained in the proposed legislation.

REPORT OF SUBCOMMITTEE TO CONFER WITH REPRESENTATIVES OF VETERANS ADMINISTRATION

Father Schwitalla, chairman of the Subcommittee, informed the Committee regarding a conference that had been had with Dr. Griffith, medical director of the Veterans Administration, and Mr. Harold V. Stirling, director of the Vocational Rehabilitation Service of the Veterans Administration, at which both of these gentlemen had expressed the hope that any criticisms which might come to the notice of the Committee on Postwar Medical Service be transmitted to them. Procedure to be used in getting out official lists of institutions to be utilized by the Veterans Administration was discussed.

The report of the subcommittee was accepted and the committee continued.

REPORT OF SUBCOMMITTEE TO CONFER WITH SURGEONS GENERAL OF ARMY, NAVY AND PUBLIC HEALTH SERVICE

The chairman called for the report of the Subcommittee to Confer with the Surgeons General of the Army, Navy and Public Health Service and, in the absence of Dr. Collier, chairman of the subcommittee, Dr. Palmer stated that it had not been possible since the October meeting to arrange the desired conferences with Admiral McIntire or Surgeon General Parran, but that it is hoped that such conferences can be arranged for around Christmas or early in January.

COMMUNICATIONS FROM MEDICAL OFFICERS

The Chairman informed the Committee that he had in his possession a number of letters sent him as Secretary pro tem by Dr. Lee that had been received from medical officers on active duty, most of which were in the nature of complaints concerning the type or lack of professional work they were doing. He requested the opinion of the Committee as to what should be done with these and similar letters that might be received. The matter was discussed by Dr. Graham, Lieutenant Colonel Gessner and Drs. West and Bierring, and it was agreed by the Committee that such communications should be sent without the names of the writers to the proper officers of the military services concerned in Washington for opinion or information, this, in turn, to be transmitted to the original writers by the Committee.

TIME AND PLACE OF NEXT COMMITTEE MEETING

It was moved by Dr. Bierring, duly seconded and carried, that the next meeting of the Committee on Postwar Medical Service be held at 535 North Dearborn Street, Chicago, on Saturday, Feb. 10, 1945.

The meeting adjourned at 1:18 p. m.

Medical Economic Abstracts

ASSOCIATED HOSPITAL SERVICE OF NEW YORK GRANTS NEW INCREASE IN BENEFITS

Increased benefits to the 1,700,000 members of the Associated Hospital Service of New York were announced November 30 by Louis H. Pink, president. Beginning December 1 subscribers are entitled to receive hospital care during a period of twenty-one days for each separate illness they may suffer instead of twenty-one days for the entire year. The policy of the organization granting benefits for ninety extra days at one-half the regular hospital rates will remain in effect for each period of hospitalization. In addition a cash allowance of \$7.25 will be paid to subscribers who may need operating room service at the hospital but who do not become bed patients. "These benefits have been granted," said Mr. Pink, "in keeping with our basic policy of sharing with members and their families all surpluses beyond those necessary for sound operation. They will be continued as long as our financial condition permits us to do so. Whenever our experience with added benefits proves favorable over a reasonable period of time, they are included in the contracts of our subscribers."

INDEMNITY VERSUS SERVICE PREPAYMENT MEDICAL PROGRAMS

The Council on Medical Service and Public Relations found at one of its regional conferences recently that there is a widespread belief that the Council favors cash indemnity prepayment medical care plans over service plans. The House of Delegates has approved both types of plans. It approved specifically the indemnity type of plan in 1938, and that approval led to an inference that the House favored that type of plan over a service plan. To correct that impression the House at its Atlantic City, 1942, session adopted a resolution approving the "principle of medical service plans on a service basis when sponsored by a constituent state medical association or a component county medical society in accordance with the recommendations relative to medical service plans adopted by the House of Delegates." The Council urges the extension and development of all types of prepayment medical care plans that meet the essentials laid down by the House of Delegates with respect to such plans.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Bills Introduced.—H. R. 56, introduced by Representative Izac, California, proposes to amend the Social Security Act to provide benefits to persons permanently crippled to a degree such that they are not able to engage in a gainful occupation similar to the benefits now available to the blind. H. R. 68 and H. R. 483, introduced by Representative Lane, Massachusetts, propose to grant temporary commissioned rank to certain male nurses serving in the armed forces. H. R. 76, introduced by Representative Lane, Massachusetts, proposes to authorize an appropriation of \$1,500,000 to construct a veterans' hospital at Lawrence, Mass. to accommodate approximately 2,000 bed patients. H. R. 103, introduced by Representative Voorhis, California, proposes permanent and total disability ratings to veterans suffering from severe industrial inadaptability as a result of war service. H. R. 125, introduced by Representative Lane, Massachusetts, proposes to recognize the high public service rendered by soldiers who volunteered and served in trench fever experiments in the American Expeditionary Forces during World War I. H. R. 140, introduced by Representative Voorhis, California, proposes to amend the Social Security Act so as to permit each state to adopt its own interpretation of the phrase "needy individuals" as used in the act. H. R. 141, introduced by Representative Voorhis, California, proposes to amend title X of the Social Security Act so as to permit each state to adopt its own interpreta-

tion of the phrases "needy individuals who are blind" and "blind individuals who are needy" as used in the act. H. R. 154, introduced by Representative Voorhis, California, proposes that the education and training provided by the Servicemen's Readjustment Act of 1944 shall be available to veterans on an equal basis without regard to their age. H. R. 168, introduced by Representative Cannon, Missouri, proposes to restore the benefits extended to veterans of the World War that were repealed by the Economy Act of 1933. H. R. 284, introduced by Representative Randolph, West Virginia, proposes to provide health programs for government employees. When action on a similar bill was sought in the Senate during the closing days of the 78th Congress, Senator Downey of California submitted an amendment which would have permitted osteopaths to participate in the health programs. H. R. 327, introduced by Representative Rogers, Massachusetts, proposes the establishment of a permanent Nurse Corps in the Veterans Administration. H. R. 363, introduced by Representative Bolton, Ohio, proposes additional pay for enlisted men in the Army assigned to the Medical Corps who are awarded the Medical Corps valor badge. H. R. 372, introduced by Representative Cannon, Florida, directs the Veterans Administration to provide vocational rehabilitation and assistance in securing suitable employment for service connected disabled veterans in need thereof. H. R. 395, introduced by Representative Dingell, Michigan, proposes to create a Unified National Social Insurance System to provide, among other things, temporary and permanent disability benefits and medical and hospitalization insurance benefits. The medical provisions of this bill are identical with those contained in the Wagner-Murray-Dingell bill introduced in the 78th Congress. H. R. 424, introduced by Representative Harless, Arizona, provides additional compensation for enlisted personnel of the Medical Department of the Army who serve in combat areas. H. R. 491, introduced by Representative Lemke, North Dakota, undertakes to prohibit experiments on living dogs in the District of Columbia. H. R. 519, introduced by Representative Mundt, South Dakota, provides for the prevention of pollution of waters of the United States. H. R. 525, introduced by Representative Norton, New Jersey, provides for cooperation with state agencies administering labor laws in establishing and maintaining safe and proper working conditions in industry and in the preparation, promulgation and enforcement of regulations to control industrial health hazards. H. R. 535, introduced by Representative Peterson, Florida, undertakes to amend veterans' regulations so as to provide that the use of an eye should be considered lost when visual acuity is 5/200 or less. H. R. 610, introduced by Representative Tolan, California, proposes to amend the United States Employees' Compensation Act so as to permit chiropractors to treat beneficiaries.

Society Proceedings

COMING MEETINGS

- Annual Congress on Industrial Health, Chicago, Feb. 13-15. Dr. Carl M. Peterson, 535 N. Dearborn St., Chicago, Secretary.
- Annual Congress on Medical Education and Licensure, Chicago, Feb. 12-13. Dr. Victor Johnson, 535 N. Dearborn St., Chicago, Secretary.
- Annual Forum on Allergy, Pittsburgh, January 20-21. Dr. Jonathan Forman, 956 Bryden Road, Columbus, Ohio, Director.
- Chicago Medical Society Annual Clinical Conference, Chicago, Feb. 27-March 1. Dr. Warren W. Furey, 30 N. Michigan Blvd., Chicago 2, Secretary.
- Middle Section, American Laryngological, Rhinological and Otolological Society, Indianapolis, January 17. Dr. Carl H. McCaskey, 608 Guaranty Bldg., Indianapolis, Chairman.
- Midwest Conference on Rehabilitation, Chicago, Feb. 12. Dr. Henry T. Ricketts, University of Chicago, Chicago, Chairman Committee on Arrangements.
- Society of Surgeons of New Jersey, Jersey City, January 31. Dr. Walter B. Mount, 21 Plymouth St., Montclair, N. J., Secretary.
- Southern Section, American Laryngological, Rhinological and Otolological Society, Charlotte, N. C., January 15. Dr. Verling K. Hart, 106 W. 7th St., Charlotte, N. C., Chairman.
- Western Section, American Laryngological, Rhinological and Otolological Society, Los Angeles, January 27-28. Dr. Aubrey G. Rawlins, 384 Post St., San Francisco, Chairman.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

COLORADO

Rheumatic Fever Diagnostic Service.—Dr. Ward Darley Jr. is the director of a rheumatic fever diagnostic service recently established by the Denver Area War Chest. The service has been organized to find cases of rheumatic fever and rheumatic heart disease among children and to see that these children are referred to a private physician or a clinic for care. Facilities are for diagnosis only, and no treatment is given. Children are referred chiefly by physicians and nurses of the schools and various public health, county and social agencies. Such children who already have a family physician are not seen in the clinic without the physician's written consent. In addition to discovering cases of rheumatic fever or its sequelae among children and sending them to physicians for cure, the service is also available to physicians who wish a careful check on patients with findings of heart disease or rheumatic fever. The patient is registered, weighed and measured, the history is taken and a physical examination is made. The urine is collected and blood obtained for a Wassermann test, sedimentation rate and blood count. One electrocardiogram including precordial leads is taken and fluoroscopy done with barium in the esophagus. While the primary purpose of these studies is to rule in or rule out rheumatic fever and rheumatic heart disease, it is to be expected that congenital heart disease and conditions which may be confused with rheumatic fever will be recognized. All results of the examinations are mailed to the physician, and the child is referred back to him. No charge is made.

DISTRICT OF COLUMBIA

Scientists Visit United States.—Seven scientists of India will spend six weeks in the United States as guests of the government. They are:

Nazir Ahmad, Ph.D., director, Indian Central Cotton Committee.
Dr. S. L. Bhatia, deputy director general, Indian Medical Service.
Sir Shanti Swarup Bhatnagar, director of scientific and industrial research directorate, Government of India.
Sir Jnan Chandra Ghosh, D.Sc., director, Indian Institute of Science, Bangalore.
S. K. Mitra, D.Sc., Ghose professor of physics, Calcutta University.
J. N. Mukherji, D.Sc., professor of chemistry, University College of Science, Calcutta.
Meghand Saha, D.Sc., Palit professor of physics, Calcutta University.

GEORGIA

Ophthalmic Seminar to Honor Dr. Abner Calhoun.—A seminar on ophthalmology will be sponsored by Emory University School of Medicine, Atlanta, April 19-21, to honor the memory of the late Dr. Abner Wellborn Calhoun, the first professor of ophthalmology at Emory. Dr. Calhoun was born April 16, 1845 and died Aug. 21, 1910. Guest speakers will be Drs. William L. Benedict, Rochester, Minn.; John H. Dunnington, New York; Harry S. Gradle, Chicago; Parker Heath, Detroit; Walter I. Lillie, Philadelphia; Col. Derrick T. Vail Jr., M. C., and Dr. Frank B. Walsh, Baltimore. All interested in ophthalmology are invited to attend as guests of Emory University.

ILLINOIS

Booklets on Health Education.—Two brochures are now available incorporating basic plans for student health education in teacher trained institutions and the school health program. They have been prepared by the Illinois Joint Committee on School Health under the direction of Dr. Roland R. Cross, chairman, director of the state department of public health, Springfield; Vernon L. Nickell, superintendent of public instruction, Springfield; Frank G. Thompson, Mount Vernon, director of the department of registration and education, and Clair E. Turner, Dr.P.H., consultant. The plans have been prepared to serve as a guide and not as a graded course of study.

Chicago

Ludvig Hektoen Lecture.—The twenty-first Ludvig Hektoen Lecture of the Frank Billings Foundation will be delivered on March 23 at the Palmer House by Dr. Joseph W. Beard, assistant professor of surgery, Duke University School of Medicine, Durham, N. C., on "The Ultracentrifugal, Chemical and Electron Micrographic Characters of Purified Animal Viruses."

Joint Meeting on the Heart.—The Jackson Park Branch of the Chicago Medical Society and the clinical section of the Chicago Heart Association will hold a joint meeting at the Windermere East Hotel, January 18. Speakers will be Drs. Chauncey C. Maher on "The Heart in the Middle Aged" and Howard Wakefield, "Concerning Certain Problems of Coronary Artery Disease."

Officers of Institute of Medicine.—Dr. William C. Danforth is the new president of the Institute of Medicine of Chicago and Dr. Daniel J. Glomset, Des Moines, Iowa, vice president. Dr. George H. Coleman is secretary and Dr. Grant H. Laing treasurer. Dr. Ludvig Hektoen is honorary chairman of the board of governors, and Dr. William F. Petersen chairman of the board of governors.

Fernel Sentenced to Prison.—Dr. Jean Paul Fernel was sentenced to prison for three years on December 29 following his conviction by a jury on twenty-one charges of violating the Food and Drug Act (*THE JOURNAL*, Oct. 14, 1944, p. 444 and Sept. 2, 1944, p. 39). Fernel's license to practice medicine had been revoked on June 1, 1938 for the third time. Fernel was said to have carried on a mail order medical business from his home at 1543 North Wells Street. A former sentence of a year and a day imposed a year ago on a similar charge will be served concurrently with that of the recent sentence.

KENTUCKY

Society News.—Dr. Lester R. Dragstedt, Chicago, will address the Jefferson County Medical Society January 15 on "Supradiaphragmatic Section of Vagus Nerves in the Treatment of Gastroduodenal Ulcer."—Dr. Winston U. Rutledge, Louisville, will discuss "Industrial Dermatitis" before the Louisville Medico-Chirurgical Society January 26, and Dr. Harry S. Frazier, Louisville, "Staphylococci Septicemia."—Dr. Edwin P. Scott, Louisville, addressed the Louisville Society of Medicine January 4 on "Meningitis."

MASSACHUSETTS

Symposium on Low Back Pain.—On January 17 the New England Society of Physical Medicine will conduct a symposium on low back pain at the Hotel Kenmore, Boston. The speakers will be Drs. John G. Kuhns on "Orthopedic Management" and William Jason Mixter, "Ruptured Intervertebral Disks," both of Boston.

One Hundred Years of Medicine.—On December 6 the Middlesex North District Medical Society held special ceremonies in the Lowell Memorial Auditorium, Lowell, to observe its one hundredth anniversary. Among the speakers on the program were Drs. Benjamin deF. Lambert and James J. Cassidy, Lowell, president of the society; Roger I. Lee, Boston, President-Elect, American Medical Association, on "Medicine Today and Tomorrow"; Elmer S. Bagnall, Groveland, president, state medical society; Morris Fishbein, Editor of *THE JOURNAL*, and Archibald R. Gardner and Michael A. Tighe, Lowell, who was toastmaster. The society had its beginning in two associations which preceded it, the Middlesex Medical Association, organized in Lexington in October 1829, and the Lowell Medical Association. The Middlesex group held its third annual meeting in Lowell on May 16, 1832, and the fifth and last meeting was held at Charlestown. In 1833 "on account of loss of time and the expense incurred by the members in going by stage to and from their then distant places of meeting" the association was dissolved. For several years there was no formal organization of physicians in this vicinity. On March 8, 1839 a special meeting of Lowell physicians was held "to organize a society for mutual improvement," which resulted in the formation of the Lowell Medical Association. This society continued until a charter was granted by the Massachusetts Medical Society on Nov. 2, 1844 for the establishment of a district society to be known as the Middlesex District Medical Society. In 1850 Middlesex County was divided into three districts, east, north and south. Lowell and eighteen neighboring towns were included in the north district and the name of the Middlesex Society was changed to the Middlesex North District Medical Society, the name it now retains. In its anniversary program it is stated that on June 6, 1845 the society advertised for free patients, and two physicians were selected at each meeting to examine them, thus establishing a clinic, a practice which seems to have ceased in 1847.

MICHIGAN

Personal.—An upholstered arm chair was presented to Dr. Plinn F. Morse, Detroit, by members of the staff of the Highland Park General Hospital at a dinner December 13 to mark his retirement from active service as pathologist to the hospital. Dr. Morse will continue as consultant.

Society News.—On January 25 Dr. Percival Bailey, professor of neurology and neurosurgery, University of Illinois College of Medicine, Chicago, will address the Michigan Society of Neurology and Psychiatry, Detroit, on "Cerebral Architectonics." Dr. Karl A. Menninger, Topeka, Kan., addressed the society, November 30, on "Psychiatry in Medical Education."

MINNESOTA

The Mayo Memorial.—A twelve story building will be constructed at the University of Minnesota Medical School, Minneapolis, to link existing units into one medical center as a permanent tribute to the late Drs. Charles H. and William J. Mayo. Costing about \$2,000,000, the memorial will be located in the center of the University Hospital Quadrangle on the medical school campus, serving as the main entrance to the school and the hospitals. Construction of the new building will be skeleton type with red tone Minnesota wire cut face brick matching that in the adjacent buildings and trimmed with Indiana oolitic limestone. The memorial will contain a memorial auditorium, research laboratories, conference rooms and offices for the clinical departments and the department of pathology, the operating rooms and major laboratories of the University Hospitals, and the administrative offices of the medical school, the school of nursing, the University Hospitals and the department of postgraduate medical education. Nine projects figure in the ultimate development, the Mayo Memorial forming the central unit, including the existing Student Health Service, the obstetric unit and outpatient clinics, William Henry Eustis Children's Hospital, Elliot Memorial Hospital, George Chase Christian Memorial Cancer Institute, Todd Memorial Eye, Ear, Nose and Throat Hospital, a future hospital addition and a proposed building for the School of Public Health. All floors of the building from the basement to the fifth floor will connect with present hospital buildings. Experimental surgery with air conditioned animal quarters will be housed in the basement or first floor of the Memorial in connection with a suite of operating rooms for teaching purposes. The department of radiology and diagnostic, teaching and research laboratories will be on the second floor. On the fourth floor will be assembled the teaching and service laboratories of the University Hospitals, laboratories for clinical diagnosis, bacteriologic examinations, biochemistry, blood examinations, metabolic studies and electrocardiography, offices and rooms for the course in medical technology and the auditorium balcony. The auditorium will be on the main floor and accommodate about 700 persons. The fifth floor will house the department of pathology with teaching and research laboratories, a lecture room and pathologic museum. The sixth and seventh floors will be devoted to operating, surgical service, conference and anesthesia rooms, laboratories, galleries and general offices of the department of surgery. The eighth floor will house the laboratories, offices and conference rooms of the department of obstetrics and gynecology and the ninth the department of ophthalmology, otolaryngology and dermatology. On the tenth floor will be the laboratories, offices and conference rooms of the department of medicine, on the eleventh the department of neuropsychiatry and on the twelfth the department of pediatrics. On the top floor of the tower will be the administrative offices of the medical school, a "campus" office for the Mayo Foundation, a faculty room and a student and faculty lounge where students, faculty and guests may gather. The Committee of Founders of the Mayo Memorial, created by the 1943 Minnesota legislature to develop a suitable memorial to the two Mayo brothers, consists of three members each from the senate and the house of representatives and twelve additional members appointed by the governor. Donald J. Cowling, LL.D., Northfield, is chairman of the committee and Dr. George A. Earl, St. Paul, secretary. On November 4 the board of regents of the University of Minnesota approved the requests of the Committee of Founders to establish a Mayo Memorial Fund to which may be credited private and public donations and appropriations. Headquarters for the Mayo Memorial Fund are at 1126 Northwestern Bank Building, Minneapolis 2.

NEW YORK

Sanitary Code Amended.—On November 17 the Public Health Council adopted amendments to its state sanitary code, effective January 1, "to make the restrictions identical in septic sore throat and scarlet fever in accordance with present knowledge concerning the etiology of these clinical conditions and to make the restrictions with regard to communicable diseases on dairv farms more in accordance with the fact that pasteurization is the most important protective barrier." Recent requirements of the state sanitary code have provided that

isolation in septic sore throat shall be "until recovery," whereas isolation in the case of scarlet fever shall be "until twenty-one days after development of the disease. . . ." Because field and laboratory studies within recent years have demonstrated that, from the standpoint of the causative micro-organisms, septic sore throat and scarlet fever are identical, it is believed that there is no longer justification for isolation provisions which are not identical in these two clinical conditions and which therefore have been grouped under one designation, "streptococcic sore throat (including scarlet fever)." The isolation period has also been modified with the stipulation that all streptococcic sore throats are to be isolated until "the mucous membranes of the nose and throat appear normal, and until all abnormal discharges from the nose, throat and ears and suppurating glands have ceased, provided that such isolations shall continue for not less than seven days and not more than ninety days." *Health News* points out that release from isolation shall be on the basis of a negative throat culture and termination must be on a clinical basis. A new regulation provides that persons dying from diphtheria or scarlet fever may in the future be exempted from the provision calling for the immediate sealing of a casket.

New York City

Harvey Lecture.—Hermann Otto Laurenz Fischer, Ph.D., research professor, University of Toronto, Ont., will deliver the fourth Harvey Society Lecture of the current series at the New York Academy of Medicine, January 18. His subject will be "Biological and Chemical Relationships Between Hexoses and Inositols."

Meeting on the Heart.—The New York Heart Association, a division of the New York Tuberculosis and Health Association, will be addressed January 26 at the New York Academy of Medicine. The speakers will be Drs. Reginald H. Smithwick, Boston, on "Surgical Treatment of Hypertension" and Harry E. Ungerleider, "Cardiac Enlargement—Its Management and Significance."

Meeting on Diabetes.—The New York Diabetes Association was addressed at the New York Academy of Medicine, January 13, by Major Isadore Arthur Mirsky, M. C., on "What is the Cause of Diabetes in Man?" and Dr. John P. Peters, New Haven, Conn., "Use of Carbohydrate in Diabetic Acidosis." A round table discussion by a panel chosen from a group of members from the council of the American Diabetes Association concluded the session.

Class of '95 to Celebrate Anniversary.—The class of 1895 of the Columbia University College of Physicians and Surgeons will hold its fiftieth anniversary dinner at the Century Club, May 15. A feature of the dinner will be the presence of a 1945 graduate of the college as a guest of the class group to answer questions that were given to the 1895 class. According to Dr. Theron W. Kilmer, class president, the class was the largest one ever to graduate at Columbia, containing 202 members.

Graduate Courses.—The New York University College of Medicine announces three postgraduate courses to start in February. One on internal medicine will be given by Dr. Charles H. Nammack and his associates. One on clinical gastroenterology, to be conducted by Dr. Zachary Sagal, was designated for practicing physicians, and the lectures will be preceded by demonstration of patients in the wards. The third course will be conducted by Dr. Otto Steinbrocker on arthritis and rheumatic disorders. Additional information may be obtained from the secretary of the New York University College of Medicine, 477 First Avenue, New York 16.

Information on Crippled Children.—On December 26 the New York City Health Department announced that there are more than 17,500 known cases of crippled and otherwise orthopedically handicapped children in the city. Based on figures of June 30, 1944 it was stated that prenatal influence and injuries associated with birth (6,246), poliomyelitis (3,914), cerebral palsy (1,819), congenital clubfoot (1,483) and scoliosis (1,474), in that order, rank highest among the causes of disability. A total of 17,578 orthopedically handicapped children under 21 years of age were registered with the division for physically handicapped children of the bureau of child hygiene, city department of health, as of June 30, 1944.

Chronic Pulmonary Diseases.—The New York Tuberculosis and Health Association announces that the thirty-fourth clinical session on chronic pulmonary diseases was held at the Cornell University Medical College Amphitheater, January 10, under the auspices of the Tuberculosis Sanatorium Conference of Metropolitan New York. The program included a discussion of x-ray films by Dr. Abraham E. Jaffin, Jersey City, N. J., chief, Hudson County tuberculosis clinics,

and talks by Drs. Horton C. Hinshaw, Rochester, Minn., on "Chemotherapy in Pulmonary Tuberculosis" and Maurice I. Smith, chief pharmacologist, National Institute of Health, Bethesda, Md., "Present Status of Research in the Chemotherapy of Sulfonamides and Sulfones in Experimental Tuberculosis."

NORTH CAROLINA

Symposium Marks Fiftieth Anniversary of Watts Hospital.—The fiftieth anniversary of the founding of Watts Hospital, Durham, will be observed February 14-15 with the presentation of the second annual medical and surgical symposium sponsored by the hospital staff. The program will be held at the Washington Duke Hotel, Durham.

TEXAS

University News.—Major Gen. George F. Lull, deputy surgeon general, U. S. Army, delivered the principal address at the second annual commencement of Southwestern Medical College of the Southwestern Medical Foundation, Dallas, December 18. Fifty-seven seniors were given the degree of doctor of medicine.

Personal.—Dr. Alvis E. Greer, Houston, has been made editor in chief of the *Medical Record and Annals*, succeeding Dr. Everett L. Goar, Houston, who has held the position for about eleven years.—Dr. Caleb O. Terrell, Fort Worth, has been appointed a member of the board of regents of the University of Texas, Austin, to succeed the late Dr. Kenneth H. Aynesworth, Waco.

The Greenwood Lectureship.—Dr. James Greenwood Jr. has donated a fund to the University of Texas Medical Branch, Galveston, to establish the James Greenwood Lectureship in neurology and neurosurgery in honor of his father, Dr. James Greenwood. The lectureship will provide for meetings both at the Baylor University College of Medicine at Houston and at the University of Texas Medical Branch in Galveston.

UTAH

Dr. Howells Resigns Salt Lake Health Position.—Dr. Thomas J. Howells has resigned as health commissioner of Salt Lake City, effective January 1. Dr. Howells, who held the position nine years, plans to enter private practice.

WEST VIRGINIA

State Free of Poliomyelitis.—Reports compiled by the state health department for the week ended December 16 show that West Virginia is free from all cases of poliomyelitis for the first time since last July. During the year 221 cases were reported in the state, with an estimated death toll of 9. This compares with 662 cases and 52 deaths in 1940. The death rate in that year was 7.8 per cent.

ALASKA

Northwest Medicine to Serve Alaska.—Beginning with its January issue *Northwest Medicine* will serve as the official journal of the Alaska Territorial Medical Association. The journal is now the official publication of the Oregon, Washington and Idaho state medical associations. Of the four territorial areas of the United States, medical journals are published by Hawaii and Puerto Rico, the latter in the Spanish language. Residents of the Virgin Islands do not have sufficient medical representation to publish a journal, and now Alaska will be officially represented in *Northwest Medicine*.

GENERAL

Public Health Nursing Day.—The American Red Cross, the National Organization for Public Health Nursing and other health agencies are cooperating in observing the first national public health nursing day January 26.

Noise Abatement Week.—The week of April 29-May 5 has been designated Noise Abatement Week, according to the National Noise Abatement Council. In past years Noise Abatement Week has been held from May 6 to May 12. George W. Handy, Buffalo, is president of the council sponsoring Noise Abatement Week.

Society for the Hard of Hearing.—Dr. C. Stewart Nash, Rochester, N. Y., was elected president of the American Society for the Hard of Hearing at its annual meeting in New York, November 10. Vice presidents are Mrs. A. E. Hunt, Newtonville, Mass., and Dr. Westley M. Hunt, New York. Other officers include Mrs. Francis E. Lee, Maumee, Ohio, recording secretary, and Mr. Raymond H. Greenman, Washington, D. C., managing director. The recent meeting included a symposium on the prevention and alleviation of

the disorders and diseases associated with deafness and a session on rehabilitation and education. The convention was concluded with an anniversary banquet marking the completion of twenty-five years of service.

National Research Council Grants for Research in Endocrinology.—It is announced that requests to the National Research Council Committee on Research in Endocrinology for aid during the fiscal period from July 1, 1945 to June 30, 1946 will be received until Feb. 28, 1945. Application blanks may be obtained by addressing the Division of Medical Sciences, National Research Council, 2101 Constitution Avenue, Washington 25, D. C. In addition to a statement of the problem and research plan or program, the committee desires information regarding the proposed method of attack, the institutional support of the investigation and the uses to be made of the sum requested. No part of any grant may be used by the recipient institution for administrative expenses. Applications for aid of endocrine research on problems of sex in the narrower sense cannot be given favorable consideration, but the committee will consider support of studies on the effects of sex hormones on nonsexual functions; for example, on metabolism.

Special Society Elections.—At the second annual meeting of the American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, November 10, Dr. Morris S. Bender, New York, was elected president. Other officers include Drs. Alfred Schattner, New York, vice president, Jacob Daley, New York, secretary, and Benjamin H. Shuster, Philadelphia, treasurer.—Brig. Gen. James S. Simmons, M. C., was chosen president-elect of the American Society of Tropical Medicine at its meeting in conjunction with the Southern Medical Association in St. Louis, November 14-16, and Dr. Rolla E. Dyer, Bethesda, Md., was installed as president. Other officers include Dr. Paul F. Russell, Washington, D. C., vice president, and Dr. Joseph S. D'Antoni, New Orleans, secretary-treasurer.—Dr. Marye Y. Dabney, Birmingham, Ala., was chosen president-elect of the Southern Medical Association and Dr. Edgar G. Ballenger, Atlanta, Ga., was inducted into the presidency. Other officers include Dr. Edward Vernon Mastin, St. Louis, vice president, and Mr. C. P. Loran, Birmingham, secretary, treasurer and general manager.—Dr. Walter B. Cannon, Boston, was reelected president of the American-Soviet Medical Society at its meeting in New York, November 11. Other officers include Dr. Abraham Stone, New York, national secretary, G. I. Shapiro, D.D.S., New York, corresponding secretary, and Dr. George I. Swetlow, Brooklyn, treasurer.—Dr. James C. Masson, Rochester, Minn., was elected president of the Western Surgical Association at its annual meeting in Chicago in December. Dr. Arthur R. Metz, 250 East Superior Street, Chicago 11, is the secretary and Dr. William M. Mills, Topeka, Kan., the treasurer.

CANADA

Society News.—Dr. Paul Letondal, University of Montreal Faculty of Medicine, was elected president of the Société Médicale de Montréal at its meeting December 19. Other officers include Drs. Armand Frappier, vice president; Origène Dufresne, general secretary; Jean Denis, assistant secretary, and Edouard Desjardins, treasurer. The society was founded in 1900 and incorporated in 1929.

Conference on Industrial Health.—The second annual conference on industrial health sponsored by the Health League of Canada (industrial division) was held at the Royal York Hotel, Toronto, December 6. The theme of the session was "Veteran's Rehabilitation" and speakers included Dr. Clarence M. Hincks, Toronto, Capt. Frank E. Coburn and Lieut. Col. Thomas H. D. Storms, R. C. A. M. C., Dr. Clarence D. Selby, Detroit, Dr. Edward C. Holmblad, Chicago, and Dr. John G. Cunningham, Toronto. One feature of the meeting was a round table discussion on a health program in an industrial plant.

Appointments to New Health and Welfare Unit.—Major General George B. Chisholm, director-general of medical services for the Canadian army, and George F. Davidson, director of the Canadian Welfare Council, have been appointed deputy ministers in the department of national health and welfare, according to the *Canadian Medical Association Journal*. The department was set up as a separate unit during the last session of parliament when the former pensions and health department was divided and made into a department of health and welfare and a department of veterans affairs. Mackenzie King, prime minister and formerly minister of pensions, has been placed in charge of the department of veterans affairs, and Hon. Brooke Claxton, former parliamentary assistant to Prime Minister King, was named health minister (THE JOURNAL, July 15, p. 803).

LATIN AMERICA

Health Activities in Latin America.—*Research on Schistosomiasis.*—A recent communication indicates that the laboratories of Jose Oliver Gonzalez, head of the department of zoology, School of Tropical Medicine, San Juan, Puerto Rico, are successfully developing a major refinement of the established detection test, simple and easy in application, to aid physicians in controlling schistosomiasis. The disease is said to be a major island affliction, affecting from 10 to 70 per cent of the Puerto Rican population in some areas and killing many slowly. The test consists of an injection of fluid containing the worm in a certain stage of its development. In 100 cases of known schistosomiasis in which the test was used it proved positive in all cases.

Availability of Penicillin.—Every person in Puerto Rico needing penicillin for treatment of sulfonamide resistant gonorrhea will be eligible for free injections, the insular health department recently announced. Large quantities of the drug have been obtained through cooperation of the federal Public Health Service and other agencies for the current antiveneral campaign. In addition to concentration on treatment for prostitutes the department of health explains that there will be enough of the drug to treat a large number of other persons in civilian life here. Only those gonorrhea cases which resist sulfonamides are eligible for the penicillin treatment. The prostitute treatment is being conducted through several hospitals throughout the island, which have been equipped to take care of several hundred women a week.

Socialized Medicine in Brazil.—Socialized medicine is being tried in certain sections of Brazil, according to Dr. Herminio Pessoa, physician attached to Santa Casa de Para Hospital in Belem. Physicians are not yet being paid well enough for the amount of work they are required to do, Dr. Pessoa is reported to have said, but, because of the system, many are receiving hospital and medical attention that would not be able to afford it otherwise. He is also reported to have said that physicians belonging to the Institute des Banquiers, an organization which provides aid for the underprivileged, are permitted to continue their private practice. Dr. Pessoa has been in the United States studying surgery at the Mayo Clinic, Rochester, Minn., for the past year, under the auspices of the Pan American Sanitary Bureau.

Congress on Neurosurgery.—The first South American Congress of Neurosurgery will be held at Montevideo, Uruguay, March 1-4. Officers of the congress include Dr. Alejandro H. Schroeder, president; Román Arana Iniguez, general secretary, and José B. Gomensoro, secretario del exterior.

Government Services

Appointments in Vocational Rehabilitation

Clifton K. Himmelsbach, Surgeon, U. S. Public Health Service, and Frank F. Furstenberg, Surgeon, U. S. Public Health Service Reserve, have been appointed assistant regional representatives in the Office of Vocational Rehabilitation, Federal Security Agency, effective in December. Dr. Himmelsbach will be assigned as assistant regional representative to the Kansas City, Mo., office and will provide assistance to the state vocational rehabilitation agencies in the organization and administration of the physical restoration phases of the vocational rehabilitation program. He will also serve as liaison with medical and hospital organizations and with other agencies interested in the vocational rehabilitation of disabled persons. Dr. Himmelsbach graduated at the University of Virginia Department of Medicine, Charlottesville, in 1931. He was clinical director of the U. S. Public Health Service Hospital, Lexington, Ky., from 1937 to 1939 and was director of research from 1939 to 1944. Dr. Himmelsbach is well known as a clinical investigator of morphine and its derivatives, with particular reference to addiction. Dr. Furstenberg has been assigned to the San Francisco office and his services will be available to all states in the western area. Dr. Furstenberg graduated at the Indiana University School of Medicine, Indianapolis, in 1931 and served internships at the Indianapolis City Hospital, Sinai Hospital, Baltimore, and the New York State Psychiatric Institute, Columbia University 1933-34. He was medical director of the Maryland State Transient Bureau 1934-33 and medical consultant to the Maryland National Youth Administration program in 1941. Prior to his assignment to the Office of Vocational Rehabilitation,

Dr. Furstenberg was health officer for the Monroe County Health Department, Key West, Fla. He is an instructor in medicine (on leave) at Johns Hopkins University School of Medicine, Baltimore.

Examination for Regular Corps Appointment as
Assistant Surgeon and Senior Assistant
Surgeon in Public Health Service

An examination to establish eligibility for appointment as medical officers in the grade of assistant surgeon (1st lieutenant) and senior assistant surgeon (captain) is hereby announced to be held on the dates specified. An applicant for assistant surgeon must be a citizen of the United States, a graduate of a recognized medical school, and must have completed, or be in the process of completing, one year of internship or its equivalent. An applicant for senior assistant surgeon must meet requirements for assistant surgeon and must have had in addition at least four years of professional training or experience. The compensation of officers in the grade of assistant surgeon is \$3,411 per annum with dependents and \$2,975.50 per annum without dependents. The compensation of officers in the grade of senior assistant surgeon is \$3,991 per annum with dependents and \$3,555.50 per annum without dependents. Appointments in the regular corps are permanent in nature and afford opportunity for a career. Promotions are at regular intervals up to and including the grade of medical director (colonel). Promotion, pay and retirement schedules for medical officers in the Regular Corps of the U. S. Public Health Service are essentially the same as those of the medical corps of the Army. Officers agree to serve where assigned by the Surgeon General. Opportunity is afforded for assignment in a wide range of professional activity including hospital, research and public health duty. Travel expenses incident to official business or change of station, including transportation of dependents and household effects, are paid by the government.

The Board of Examiners will be in the following places at 9 a. m. on the dates specified. Candidates should arrange to have their physical examination completed at any one of the following listed places on or before the date shown:

- February 5, 6, Boston (Brighton), Marine Hospital, 77 Warren Street.
- February 7, 8, 9, 10, New York (Stapleton, Staten Island), Marine Hospital.
- February 12, 13, Washington, U. S. P. H. S. Dispensary, Fourth and D streets S.W.
- February 14, 15, Baltimore, Marine Hospital, Wyman Park Drive and 31st Street.
- February 16, 17, Norfolk, Marine Hospital, Hampton Boulevard-Larchmont.
- February 21, 22, Savannah, Marine Hospital, York and Abercorn streets.
- February 23, Atlanta, Malaria Control in War Areas, 605 Volunteer Bldg.
- February 26, 27, Cleveland, Marine Hospital, Fairhill Road and E. 124th Street.
- February 28, Detroit, Marine Hospital, Windmill Pointe.
- March 1, 2, 3, Chicago, Marine Hospital, 4141 Clarendon Avenue.
- March 5, Washington, U. S. P. H. S. Dispensary, Fourth and D streets S.W.
- March 12, 13, 14, Kirkwood (near St. Louis), Marine Hospital, 525 Couch Avenue.
- March 15, Louisville, Marine Hospital, Portland Avenue and 22d Street.
- March 16, Lexington, U. S. P. H. S. Hospital, Leestown Pike, Lexington, Ky.
- March 17, Memphis, Marine Hospital, Delaware and California streets.
- March 19, 20, Fort Worth, U. S. P. H. S. Hospital.
- March 21, 22, Galveston, Marine Hospital, 45th Street and Avenue N.
- March 23, 24, New Orleans, Marine Hospital, 210 State Street.
- March 26, Mobile, Marine Hospital, St. Anthony and Bayou streets.
- March 28, Washington, U. S. P. H. S. Dispensary, Fourth and D streets S.W.
- April 3, 4, Los Angeles, U. S. P. H. S. Relief Station, 406 Federal Building.
- April 5, 6, 7, San Francisco, Marine Hospital, 14th Avenue and Park Blvd.
- April 10, 11, 12, Seattle, Marine Hospital, Judkins Street and 14th Avenue South.
- April 16, Minneapolis, Office of Indian Affairs, 218 Federal Building.
- April 18, Washington, U. S. P. H. S. Dispensary, Fourth and D streets S.W.
- April 23, 24, 25, Written examination.

Persons who complete the physical examination and certain other portions of the examination will be permitted to participate later in the three day written examination beginning April 23 either at the place where the physical examination was conducted or at some other nearer point.

Applicants may obtain application blanks by writing to the Surgeon General, U. S. Public Health Service, Bethesda Station, Washington 14, D. C. These forms may be filled out and delivered to the Board of Examiners or may also be obtained from the board at the time the applicant appears before the board. Applicants wishing to use National Board grades in lieu of written examination should present their certificates to the board. Applicants should bring their medical school diploma with them.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Dec. 9, 1944.

Surgery with the Parachute Troops

When parachute troops go into action behind enemy lines it may be some days before normal channels of casualty evacuation can be established. The medical services of the air borne formation are responsible for the medical and surgical care of casualties until contact has been made with the medical services of the supporting force. The *Army Medical Department Bulletin* states that two parachute surgical teams are attached to each field ambulance to make certain that efficient surgical aid is always available. A team consists of one surgeon and five orderlies; when it goes into action an anesthetist is attached. One of the orderlies looks after resuscitation and preoperative treatment, two are chosen for nursing ability, and all are endowed with the intelligence, temperament and physique required of all parachutists. All the men are trained so that they can do one another's duties; their capacity to improvise and adapt themselves has been an important factor in the success of these teams.

Equipment has been cut to essentials and is light enough to be easily handled in difficult country even under fire. A light operating theater, essential instruments, anesthetics, plaster, dressings, plasma, transfusion apparatus and fuel are carried. Loss of equipment in transit often calls for a good deal of improvisation. The essential instruments include two excision sets, extra abdominal and fracture sets, trays, bowls, dishes, a sterilizer and boiled water container. Linen thread is used for most suturing, but small quantities of atraumatic catgut and silkworm gut are included. As water supply is often a problem, collapsible containers are carried for storage. Heat and light are obtained from collapsible primus stoves, paraffin pressure lamps and electric headlamps. Feeders, bedpans and special ward equipment are also carried, but beds and bedding must be improvised on the spot.

Experience has already taught much: acriflavine tablets are the most economical and useful antiseptic for general use; only 11 of 150 cases in one operating session required any other anesthetic than pentothal alone; chloroform is preferable to ether for inhalation anesthesia because of the risk of fire. In 1 case a parachute surgical team functioned for two days in a farm building, the work being shared by two surgeons. In spite of a nearby battle, thirty-five operations were done in twenty-one hours operating time, with only two deaths. Chest, neck, head and limb wounds were treated. Two men with abdominal wounds could not be sufficiently resuscitated for operation. Four fifths of the casualties were operated on about five hours after they were wounded.

The Sinking of a German Hospital Ship

An official statement has been issued with regard to the sinking of the German hospital ship *Tuebingen* in the Adriatic on November 18 by allied aircraft. The German authorities have been notified that a full inquiry is proceeding, and an expression of regret from the British government has been conveyed. The *Tuebingen* was intercepted by a British destroyer west of Crete on October 27 in the course of evacuating German sick and wounded from Salonika to Trieste. In accordance with the Hague convention, these casualties, numbering 1,023, were removed and made prisoners of war, and the ship was released after examination with instructions to continue her voyage to Trieste. However, she put into the Yugoslav port of Bar and embarked an additional 337 sick and wounded. She was again intercepted and taken into the Italian port of Bari, and the

casualties were removed. She was again released on November 17 with instructions to sail to Trieste. Next day when off the Italian port of Pola she was sighted by air forces before sunrise. She was not illuminated, and in the poor light the flight leader was unable to identify her. He reported to base and asked for instructions. Owing to atmospheric conditions the message was received incorrectly and indicated to the controlling officer that a high speed launch had been sighted in the middle of the gulf of Venice. Having ascertained that no allied launch was in the neighborhood the controlling officer gave permission to attack. This was done, and the ship was sunk. It is understood that the casualties among the crew were very light. This appears to be the only case of the sinking of a German hospital ship in the five years of war. Unfortunately the same cannot be said of British hospital ships, nor can it be said that their sinking was by mistake.

Meeting of Foreign Doctors in London

The war has brought a large number of foreign doctors to this country, refugees from the part of Europe which was occupied by the Germans. We have done what we could to welcome them at medical societies and otherwise. With the liberation of Europe approaching completion, these men are hoping soon to return home. At the House of the British Medical Association what may be regarded as an informal farewell meeting was held and was attended by representatives of eight countries. Dr. Dain, chairman of the council, said that if there was a wider diffusion of the spirit that permeated medicine the prospects of future peace might be made secure. There were no frontiers to medical knowledge, no monopolistic restrictions to medical discoveries, he emphasized. If out of that meeting came a movement for giving permanent expression to the bonds which hold together doctors of different countries the British Medical Association would feel it a privilege to give all the help it could, Dr. Dain said. Dr. Alfred Cox, a former secretary of the British Medical Association, gave a short history of the Association professionnelle internationale des médecins and recalled how the proposal to hold the annual conference of 1938 in Prague was defeated by the German delegate, who considered this an insult to the master race. In reply the Norwegian minister of health, Dr. Karl Evang, said that in the new kind of world which they hoped to construct after the war medical services would be to some extent reconstructed also. The other foreign delegates present were Dr. C. Meissner, chairman of the Polish Medical Association, Dr. J. Ungar of Czechoslovakia, Col. C. F. Koch of the Dutch army, Dr. M. Selkin of Yugoslavia, Col. B. A. Osipov of the Soviet military mission and Dr. A. D. de Smet of Belgium.

Marriages

RICHARD NEWTON ABBOTT, West Newton, Mass., to Miss Myrtle Louise von Hagen of Middletown, Conn., October 28.

EDGAR LEE ETIER JR., Fort Worth, Texas, to Miss Patricia Catherine Nesrsta of San Antonio, October 20.

MILTON LAWRENCE McCALL, Philadelphia, to Miss Jane Maxine French of Ardmore, September 30.

WILLIAM H. GEHRON JR. to Miss Betty Y. Schwoerer, both of Williamsport, Pa., October 7.

CHARLES BUNCH to Miss Sarah Elizabeth Sherrill, both of Charlotte, N. C., November 23.

WENDELL B. HOLMES, Tylertown, Miss., to Miss Joy Ratliff of McComb, November 5.

H. RAYMOND MUTCHLER, Dover, N. J., to Miss Flora B. Beebe, October 13.

JAMES J. SMITH to Miss Grace Louise Ruhle, both of Brooklyn, November 3.

ROBERT KAREN to Miss Helen Gregor, both of Milwaukee, September 10.

Deaths

Richard Frothingham O'Neil * Boston; Harvard Medical School, Boston, 1897; member of the House of Delegates of the American Medical Association in 1912 and chairman of the Section on Urology, 1920-1921; member of the International Society of Urology and the New England Surgical Society; member, formerly secretary and president of the American Association of Genito-Urinary Surgeons; member and past president of the American Urological Association; formerly secretary and president of the New England section of the American Urological Association; fellow of the American College of Surgeons; served in the Spanish-American War and World War I; specialist certified by the American Board of Urology, Inc.; served as genitourinary surgeon in the outpatient department at the Massachusetts General Hospital, where he later had been visiting genitourinary surgeon, associate urologist and since 1934 member of the board of consultation; formerly on the staff of St. Elizabeth's Hospital; author of a chapter on "Renal Tuberculosis" in "Cabot's Modern Urology"; died in December, aged 70.

Peter Irving * New York; Columbia University College of Physicians and Surgeons, New York, 1903; since 1937 secretary and general manager of the Medical Society of the State of New York; specialist certified by the American Board of Internal Medicine; member of the House of Delegates of the American Medical Association in 1938, 1939 and 1940; fellow of the New York Academy of Medicine and the American College of Physicians; member of the alumni association and consulting physician at the Roosevelt Hospital, where for many years he was lecturer on medical subjects to the undergraduates and from 1919 to 1937 physician to the training school; consulting physician to the Seton and New York hospitals; managing editor of the *New York State Journal of Medicine*; in 1943 appointed by Governor Dewey as a member of a commission to investigate the management and affairs of the department of mental hygiene of the state of New York; died in the Roosevelt Hospital December 28, aged 66.

John Minos Fermster Gill * Wichita Falls, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1889; captain, medical corps, U. S. Army, during World War I; psychiatrist on the board of examiners for the U. S. Army enlisting and induction station at Abilene, Texas, from March through July in 1942; at one time city physician at Burkburnett; formerly on the staffs of the Kings Daughters Hospital, Temple, Texas, Confederate Home Hospital, Austin, Abilene State Hospital, Abilene, San Antonio State Hospital, San Antonio, and the Rusk State Hospital, Rusk; retired Nov. 1, 1944 as a member of the staff of the Texas State Hospital; died in the Veterans Administration Facility, Waco, December 10, aged 76, of arteriosclerosis.

William Province Garshwiler * Indianapolis; Medical College of Indiana, Indianapolis, 1896; professor emeritus of urology and formerly clinical professor of genitourinary surgery at the Indiana University School of Medicine; specialist certified by the American Board of Urology, Inc.; member of the American Urological Association; fellow of the American College of Surgeons; served as consulting genitourinary surgeon, Indianapolis City, St. Vincent's and Robert W. Long hospitals, William H. Coleman Hospital for Women and the James Whitcomb Riley Hospital for Children; died at his home in Southport, Ind., December 10, aged 76, of cerebral hemorrhage.

Blanche M. Haines, Three Rivers, Mich.; Woman's Hospital Medical College, Chicago, 1886; formerly head of the division of maternal and infant hygiene of the U. S. Children's Bureau at Washington, D. C., and director of the Michigan Bureau of Child Hygiene and Public Health Nursing; served as city health officer, member and secretary of the board of education; member of the American Association of University Women, fellow and life member of the American Public Health Association; member of the Institute of American Genealogy and Daughters of the American Revolution; died November 9, aged 78.

Oscar Robert R. Troje * Fairfield, Ala.; University of Kansas School of Medicine, Kansas City, 1907; specialist certified by the American Board of Radiology, Inc.; member of the American Roentgen Ray Society, Radiological Society of North America, Inc., and the American College of Radiology; lieutenant commander, medical corps, U. S. Naval Reserve, not on active duty; for many years chief radiologist at the Employees' Hospital of the Tennessee Coal, Iron and Railroad Company, where he died December 12, aged 59, of cerebral hemorrhage.

Rubin Evans, New York; Université de Lausanne Faculté de Médecine, Switzerland, 1941; served an internship at the Israel Zion Hospital in Brooklyn; commissioned a first lieutenant in the medical corps, Army of the United States, on Aug. 22, 1942 and began active duty on Sept. 3, 1942; killed in action in Italy May 15, 1944, aged 27. [It has been impossible to obtain a photograph of Dr. Evans.]

CAPT. KENNETH P. SWAFFORD
M. C., A. U. S., 1916-1944

Council on Medical Education and Hospitals

APPROVED SCHOOLS FOR X-RAY TECHNICIANS

The Essentials of an Acceptable School for X-Ray Technicians were adopted by the House of Delegates of the American Medical Association during the June 1944 session and were

published in THE JOURNAL, June 24, 1944. In accordance with these Essentials a survey was made of existing schools. The American Registry of X-Ray Technicians and the American College of Radiology have extended their cooperation in the formation of the Essentials and in the survey of schools. Although this is the first published list of approved schools, other training programs for x-ray technicians will be added when it has been determined that they fulfil the Essentials.

The following schools substantially conform to the minimum requirements and have been approved by the Council on Medical Education and Hospitals:

APPROVED SCHOOLS FOR X-RAY TECHNICIANS Council on Medical Education and Hospitals of the American Medical Association

Name and Location of School	Entrance Requirements	Length of Training in Months	Maximum Enrolment	Classes Begin	Tuition	Certificate, Diploma, Degree
CALIFORNIA						
California Hospital, Los Angeles *	High school graduate	24	6	Jan., July	\$ 50	Diploma
College of Medical Evangelists, Los Angeles *	High school graduate	12	6	Every 2 mos.	\$100	Certificate
Mercy Hospital, Sacramento *	High school graduate	12	4	Jan., July	None	Diploma
COLORADO						
Colorado General Hospital, Denver	1 year college	12	6	Every 2 mos.	None	Certificate
St. Anthony's Hospital, Denver	High school graduate	12	4	Varies	None	Diploma
St. Luke's Hospital, Denver	High school graduate	12	2	Varies	None	Certificate
CONNECTICUT						
Grace Hospital, New Haven	High school graduate	12	6	Quarterly	None	Certificate
New Haven Hospital, New Haven *	High school graduate	12	2	Varies	None	Certificate
GEORGIA						
Crawford W. Long Memorial Hospital, Atlanta	2 years college	12	3	Varies	None	Certificate
Georgia Baptist Hospital, Atlanta	2 years college	12	2	Varies	None	Certificate
Grady Memorial Hospital, Atlanta *	High school graduate	12	3	Every 4 mos.	None	Diploma
Piedmont Hospital, Atlanta	1 year college	12	2	Varies	None	Certificate
University Hospital, Augusta *	High school graduate	12	6	Varies	None	Certificate
IDAHO						
St. Alphonsus Hospital, Boise	1 year college or R.N.	12	2	Fall and Spring	\$100	Diploma
St. Luke's Hospital, Boise	1 year college	15	2	June	None	Certificate
ILLINOIS						
St. Joseph's Hospital, Alton *	High school graduate	18	2	Jan., Aug.	\$150	Certificate
Angustana Hospital, Chicago	Registered nurse	12	2	Fall and Spring	None	Diploma
Chicago Memorial Hospital, Chicago *	High school graduate	12	3	Varies	None	Diploma

IDENTICAL TWINS

To the Editor:—In an editorial comment in *THE JOURNAL*, Dec. 2, 1944 you call attention to a highly interesting observation on the Giles identical twins, namely the remarkable resemblance to each other in the successive steps of their intellectual development and accomplishment. To a geneticist this information is certainly of interest. I wish to add to the striking resemblance in all such cases of normal life instances in pathologic life of identical twins.

In a contribution presented at the May 1925 meeting of the Philadelphia Psychiatric Society (*Am. Med.* 20:603 [Oct.] 1925) I submitted in great detail records of two pairs of twins. Briefly, one group consisted of two brothers who showed equal intellectual ability. At the age of 19 one commenced to show signs of psychotic disorder, namely negligence at work, paroxysms of violent anger, sleeplessness, then carelessness with regard to his clothes, gradual loss of interest in everything and finally hypochondriacal delusions with hallucinations.

His brother at about the same time developed at first a state of depression and became very irritable, apathetic and indolent. Soon he became delusional and hallucinatory. The condition of the two brothers remained unaltered for eight months. Both had short periods of remission but no complete recovery.

The second pathologic example of identical twins concerned two sisters. At the age of 10 and 14 they had short periods of mental depression. At the age of 18, following the death of their father and because of inability of the mother to support them, they were sent away, each to a different relative. In about a year one began to show signs of depression, which at times would become so profound that attempts at self destruction were made. The sister, after a period of eighteen months, showed also signs of depression alternating with periods of manic excitement. Neither of the two made a complete recovery.

The two examples of pairs of identical twins in pathologic states, the first in dementia precox, the second in manic-depressive psychosis, are impressive, demonstrating the fact that resemblance may be not only of a morphologic but also of a morbid psychologic character. Emphasis may be laid on the fact that similar physical organizations of the nervous system may lead to similar pathologic disorders. The occurrence of such a deep parallelism speaks strongly in favor of single ovum twins, especially when the two are of the same sex. We are dealing here either with an intrinsically abnormal ovum or with a normal ovum fertilized by an abnormal spermatozoon by division. From the genetic standpoint identical twins are indeed the same individual in two bodies.

HERNIATION OF INTERVERTEBRAL DISKS

To the Editor:—I am writing to ask that proper credit be given for the manipulation treatment described and illustrated in my article on "Diagnosis of Herniation of Lumbar Intervertebral Disks by Neurologic Signs" in the December 2 issue of *THE JOURNAL*. In my article Dr. Abts was quoted as saying that the method was not original but the reference could not be found. Since publication, a letter from Dr. B. S. Troedson of Orange, N. J., has called my attention to his presentation of this method in the *Archives of Physical Therapy, X-Ray, Radium* (18:10 [Jan.] 1937) titled "Lumbosacral Derangement and Its Manipulative Treatment."

OIL BURNER FUMES AND CANCER OF THE LUNG

To the Editor:—Apropos of the editorial comment in *THE JOURNAL* November 25 (p. 838) I have tried to obtain data on the possible contribution of oil burner fumes to cancer of the lung. It seems unquestionable that such form of cancer is increased, leaving, of course, aside the old question of Bloodgood as to whether better diagnosis is involved, but the significant rise in such diagnoses invites one to try to correlate such factors as newer sources of carcinogenic materials. The suggestion that tar used on the highways has been an ever increasing source of such substances is scarcely valid for two reasons: (1) the use of tar is decreasing each year; (2) increase in lung cancer has occurred among Canadians living far from roads on which tar is used. Whether any one has given attention to oil burner fumes, poured in immense amounts into our atmosphere, is the question. The use of crude oil has increased and combustion is incomplete. It is a possible valid suggestion.

WITHROW MORSE, PH.D., New York.

PENICILLIN: A FORECAST FORTY-ONE YEARS BEFORE!

To the Editor:—The following extract is a curious illustration of this, and also of the fact that the practical usefulness of an observation depends on its practical use! In Pflüger's *Archiv* of 1888, volume 43, there is an "arbeit" by Max Bierfreund, working on rigor mortis in the Physiologic Institute of Königsberg in Prussia, under the inspiration of L. Hermann. One of his points was that the resolution of the rigor is not due to putrefaction. As an evidence he cites an instance of rabbit muscles which gave no sign of putrefaction after six to eight days, and in explanation he remarks (page 212): "Mold fungi, which flourish excellently on acid mediums, appeared on the muscles on the second day and multiplied so rapidly that the muscles were soon enveloped as by a white mantle. The mold fungi, in their turn, had prevented the development of putrefactive organisms."

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and board of examiners in the basic sciences were published in *THE JOURNAL*, December 30, page 1168.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Part I. Various centers, Feb. 19-21. Part III. Boston, Jan. 23-25. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: New York, June 8-9. Final date for filing application is March 12. Sec., Dr. George M. Lewis, 66 E. 66th St., New York 21.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: Spring. Final date for filing application is Feb. 1. Sec., Dr. Paul C. Bucy, 912 S. Wood St., Chicago 12.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Written. Part I. Various centers, Feb. 3. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

AMERICAN BOARD OF OTOLARYNGOLOGY: New York, June 5-8. Final date for filing application is March 1. Chicago, Oct. 3-6. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City, Ia.

AMERICAN BOARD OF PEDIATRICS: Chicago, May 19-20. Final date for filing application is Jan. 19. Sec., Dr. C. A. Aldrich, 115½ First Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF RADIOLOGY: Oral. New York, June 3. Final date for filing application is May 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave. S.W., Rochester, Minn.

AMERICAN BOARD OF SURGERY: Various centers, March 20. Final date for filing application is Jan. 15. Sec., Dr. J. S. Rodman, 225 S. Fifteenth St., Philadelphia 2.

AMERICAN BOARD OF UROLOGY: Oral. Chicago, Feb. 19-22. Sec., Dr. G. J. Thomas, 1409 Willow St., Minneapolis 4.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts (West Virginia): Compensability of Silicosis.—Staples was employed for about twelve years in four different mines operated by the employer and was inducted into the United States armed forces in May 1942. He was discharged from service about seven and a half months later suffering from silicosis. He was advised that he should not work in a mine and secured other employment. He instituted proceedings under the workmen's compensation act of West Virginia, alleging that the silicosis from which he was suffering was contracted from his previous employment. The compensation commissioner of West Virginia made findings on the nonmedical questions involved in the case and referred the matter, so far as the medical aspects were concerned, as is required by the workmen's compensation act, to the silicosis medical board, which, after examination and investigation, reported findings and conclusions to the commissioner, who then made an award for silicosis in the second stage. The stages of silicosis compensable under the West Virginia compensation act are defined therein as follows:

"An employee shall, for the purposes hereof, be deemed to have silicosis: (1) In the first stage when it is found by the commissioner that the earliest detectable specific signs of silicosis are present whether or not capacity for work is or has been impaired by such silicosis; (2) In the second stage when it is found by the commissioner that definite and specific physical signs of silicosis are present, and that capacity for work is or has been impaired by that disease; . . ." (Acts, 1935, chapter 79, section 7).

The employer made timely objections to the findings and the award, and a hearing was held on those objections. At that hearing it appeared that the claimant suffered from shortness of breath, asthmatic sounds in his chest and limited chest expansion. A roentgenogram of his chest showed nodular formations in the middle two thirds of his lungs. One member of the silicosis medical board testified that he believed that silicosis in any stage impaired the capacity to work in a person suffering from that disease. The two other members of that board testified that their examination demonstrated physical signs of silicosis in the second stage, one of those physicians indicating that he relied entirely on the condition of the lungs as shown by the roentgenogram. Two physicians, who had examined the claimant and who were called on behalf of the employer, testified that the claimant was suffering from first stage silicosis rather than from the second stage of that disease, basing their conclusion on roentgenographic examination and their inability to demonstrate an impairment of the claimant's capacity to work. The commissioner affirmed his former finding, and on appeal the workmen's compensation appeal board affirmed the order of the commissioner. The employer then appealed to the Supreme Court of Appeals of West Virginia.

The employer contended that there was no evidence adduced at the hearing to justify the board's findings, arguing that there were no definite and specific physical signs of silicosis shown unless the roentgenographic examination may be so considered and that there was no showing of impairment of the claimant's capacity to work. The employer inveighed against the use of a roentgenogram as sufficient to show the "definite and specific physical signs" of silicosis as required by the statute quoted. We do not agree with that contention, said the court. The x-ray is of great value in medical science and affords a basis for a reasonably definite diagnosis of certain diseases with which persons are afflicted. The court then went on to discuss provisions in the compensation act relating to the use of x-ray when a claim for compensation for silicosis is made. An applicant for benefits for disablement from that disease, the court continued, by statute must submit to examination by x-ray, if required by the silicosis board (Acts, 1935, chapter 79, section

13). Reports of examination by x-ray made by physicians acting on behalf of a claimant or his employer, if in possession of either or under his control, are required to be produced as evidence on reference to the board, and the board is required to file such reports with the commissioner (*ibid.*, sections 13 and 14). It is quite clear from a casual reading of the statute that the legislature attached importance to the use of x-ray in ascertaining whether a claimant for benefits on account of a silicotic condition is actually suffering from that disease. The use of x-rays in examination of persons allegedly suffering from silicosis is indicated by the following excerpt from Attorneys' Textbook of Medicine, ed. 2, Gray, at page 1068:

The changes within the lung upon inhalation of minute silica particles, due to their destructive action, may best be demonstrated during life by the x-ray.

The use of the x-ray to determine the condition of the internal organs of living persons is a means to an end rather than the end itself. The roentgen photographs obtained by the use of such rays is a portrayal of the physical condition, which become definite and specific physical signs to a person experienced and learned in the science of roentgenology. Without taking the statutory definition into consideration, continued the court, there is convincing evidence in the record that from a pathologic standpoint there is a marked difference in the appearance of the lungs of a person suffering from silicosis in the first stage and that of a person suffering from that disease in the second stage. It suffices to say that the x-ray examination of the claimant demonstrates definite and physical signs of silicosis in its second stage, but the second statutory requirement relating to the impairment of capacity to work does not appear from such examination, nor does it necessarily follow that such impairment exists by reason thereof. However, we believe that sufficient definite and physical signs of silicosis may, in some instances, appear from an x-ray examination and show the disease as sufficiently advanced that impairment of working capacity is clearly indicated. Such, however, is not the case here. There is no convincing evidence that the claimant's capacity to work was impaired. There was no evidence as to lack of energy, lassitude, serious shortness of breath or other physical impairment. It is true that all members of the board testified that in their opinion claimant's capacity to work was impaired. One member stated that in his opinion a person suffering from any stage of silicosis suffered such impairment. The other two members of the board gave a generalized opinion that claimant's capacity to work was impaired, basing their opinion on the condition of claimant's lungs as disclosed by the roentgenogram. On the other hand, there is positive, unequivocal testimony by the two physicians called for the employer that the employee suffered no impairment in his working capacity. We do not mean to say or imply that impairment of working capacity cannot be shown solely by a roentgenogram, but we are constrained to say that such impairment must be shown to be substantial and practical rather than slight and theoretical. It is probably correct from a scientific standpoint to say that any disease in its earliest stages diminishes the working capacity of the afflicted person, but we think that when measured by the plain import of the statute such capacity as may have been possessed by a person prior to the onset of the disease must be so lessened that the afflicted person is in a measure disabled from doing the work he was theretofore capable of doing. The statute, obviously, does not require that a person be totally disabled from doing any work, but it must appear that claimant's capacity for work is or has been actually impaired in such a degree as to lessen his ability to perform the duties incident to ordinary work. The impairment of claimant's capacity to work is not shown in the record, since there is no sufficient factual premise for the conclusion stated by the members of the silicosis medical board that there was an impairment of capacity.

The court accordingly reversed the award of compensation and remanded the case for the production of further evidence with respect to the impairment of the claimant's capacity to work.—*Staples v. State Compensation Commissioner*, 31 S. E. (2d) 433 (W. Va., 1944).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Bactericidal Action of Penicillin on Bacteria Present in Urinary Infections.

Helmholz and Sung point out that penicillin appears in much higher concentrations in urine than in any other body fluids; its concentration in the blood never approaches that found in the urine. With a normal renal function an output in the urine of 58 per cent of the 40,000 to 100,000 units of injected penicillin a day should give a concentration of from 20 to 60 units per cubic centimeter in the urine. In view of these high concentrations attainable in the urine, it would seem logical to infer that penicillin would be an ideal urinary antiseptic. The authors describe in vitro studies on the bacterial flora encountered in infections of the urinary tract. Thirty strains of *Streptococcus fecalis*, 39 strains of *Escherichia coli*, 13 strains of *Proteus ammoniae*, 18 strains of *Aerobacter aerogenes*, 3 strains of *Pseudomonas aeruginosa* and 11 strains of *Staphylococcus aureus*, all originally isolated from the urine of patients with various infections of the urinary passages, were employed in these experiments. It was found that for *Str. fecalis* a concentration of 3 Oxford units of penicillin per cubic centimeter of urine is bactericidal; for *Pr. ammoniae* 8 units per cubic centimeter of urine is the minimal bactericidal concentration of penicillin; for *Esch. coli* there seems to be a line of demarcation between the resistant and the susceptible strains at a level of 30 Oxford units of penicillin per cubic centimeter of urine. *A. aerogenes* and *Ps. aeruginosa* are very resistant to the action of penicillin. *Staph. aureus* has served satisfactorily in this investigation as a control for the other organisms under study as to their respective resistance and susceptibility toward the action of penicillin. The growth of this organism itself is inhibited at a concentration of 0.033 Oxford unit of penicillin per cubic centimeter of urine. The bactericidal action of penicillin at the low level of its concentration in urine presents therapeutic possibilities for the treatment of infections due to *Staph. aureus*, *Str. fecalis* and *P. ammoniae*. The resistance of *Esch. coli*, *A. aerogenes* and *Ps. aeruginosa* to penicillin practically rules it out as a means of treating these infections.

Renal Amyloidosis.—In their study of 379 cases of renal amyloidosis Auerbach and Stemmerman observed that the condition generally develops as part of a generalized process in which there is also involvement of the spleen, the liver and the adrenals. In the majority of cases the extent of the amyloid involvement of the kidneys lags behind that of the liver and spleen. Most persons in whom renal amyloidosis develops die of the underlying disease, which in most instances is tuberculosis. Thus a large proportion of patients with amyloidosis show at necropsy only a minimal or moderate renal involvement. The amyloid process continues for a long period in relatively few cases and it is in these long-standing processes that renal insufficiency usually develops. These patients often succumb not to the underlying disease but to uremia. During progressive deposition of amyloid the typical clinical picture of nephrosis develops in a number of patients. In the early stages of renal amyloidosis there are often no signs or symptoms which would lead one to diagnose the condition. Since the deposition of amyloid in the liver and spleen is usually more advanced, clinical observation of hepatomegaly or splenomegaly may lead one to suspect generalized amyloidosis. The authors found hepatomegaly and splenomegaly in only one third of their patients and do not consider these signs reliable aids in establishing the diagnosis. In cases of minimal and usually in cases of moderate renal amyloidosis the signs and symptoms of renal involvement first lead to the diagnosis. Observations by the authors substantiate the statement of Altnow, Van Winkle, Maly and Williams that if in the course of tuberculosis both albumin and casts appear in the urine in considerable amounts a diagnosis of renal amyloidosis may be entertained. Diminished urinary concentration is almost always present when albumin and casts appear in the urine. The loss of albumin in the urine causes a decrease in the total amount of protein in the blood, a change observed almost without exception in cases of advanced renal amyloidosis. With this reduction there is a tendency toward inversion of the albumin-globulin ratio. Edema and the retention of waste products of the metabolism usually appear within the final month of life and together constitute an extremely bad prognostic sign. Whether or not the patient succumbs to amyloid uremia depends on the patency of the glomerular capsular space. When this has been obliterated by depositions of amyloid, death from uremia is inevitable.

Gelatin as a Substitute for Plasma.—Jacobson and Smyth administered intravenously a 5 per cent solution of purified bovine osseous gelatin to 45 normal persons and to 50 patients in shock. Gelatin solution increased effectively the plasma

volume for at least twenty-four hours in persons not in shock or suffering from any cardiovascular disease. Approximately 80 per cent of the injected gelatin was recovered from the urine in forty-eight hours. There was no evidence to indicate that gelatin solution administered intravenously was metabolized. The increases in plasma volume which occur after infusions of gelatin solutions compare favorably with those observed following intravenous injections of pectin solution and are greater than those which follow intravenous crystalloid infusions. Clinical experience with the 50 persons who were in shock indicates that gelatin solution effectively increases the plasma volume and thereby corrects the major circulatory defect in this condition. The authors believe that gelatin fulfils many of the essential requirements of a substitute for human plasma and warrants an extensive clinical trial in the treatment of shock.

*Amicrobic Pyuria. E. N. Cook.—p. 588.

*Biologic Differentiation of Benign and Malignant Growths. H. S. N. Greene.—p. 595.

Amicrobic Pyuria.—Cook stresses that in the presence of an infection of the urinary tract the site of the infection must be established. He and his colleagues have seen a number of women patients who have been taking mandelic acid or one of the sulfonamides to the point of tolerance in an effort to eradicate an infection of the bladder and kidneys which did not exist. These patients have burning and frequent urination and pus in the urine. It often is found that only voided specimens of urine were examined, and when a catheterized specimen is examined it is entirely free of pus or organisms. Local treatment usually relieves the existing urethritis. When females have pyuria or other symptoms of urinary infection a specimen of catheterized urine must be examined and when males have these symptoms the two glass test of urine should be done routinely before treatment is instituted in order to determine whether the infection involves the kidneys, ureters or bladder. Simple Gram's staining of the urinary sediment should be done in every suspected case. Examination of slides after Gram's staining will divide the cases into those with demonstrable organisms and those without demonstrable organisms. Physicians have been taught that sterile or amicrobic pyuria is indicative of a tuberculous infection of the urinary tract. This is the usual cause but it does not account for all such cases. Because of the occasional difficulty in finding the tuberculous organisms in stained slides of urine and the length of time required to carry out the guinea pig test, a tentative diagnosis of tuberculosis is made. Failure to find certain clinical signs of tuberculosis of the urinary tract should tend to exclude this condition even before the laboratory reports are received. Cystoscopic findings in cases in which nontuberculous, sterile pyuria is present are a reduced vesical capacity, extreme irritability and diffuse involvement of the vesical mucosa with redness, edema and at times ulceration. The chemotherapeutic compounds that are so efficacious in combating the ordinary infections of the urinary tract are of little value in the treatment of amicrobic pyuria. Local treatment gives only palliation, but the intravenous administration of arsenical compounds is almost specific. The author makes a plea for the appreciation of the part which foci of infection play in many of these cases. Permanent cure will frequently be impossible unless existing foci are eradicated. The teeth, tonsils, prostate gland and uterine cervix are the most common foci.

Biologic Differentiation of Benign and Malignant Growths.—Greene states that in his laboratory spontaneous cancers of the breast and of the uterus have occurred in the rabbits with the greatest frequency. A characteristic feature of

these cancers is a well defined developmental history. They do not arise as a sudden transition of normal cells but represent the final step in a progressive developmental process during the course of which the primary neoplastic focus passes through successive stages of anaplastic cellular change, local tissue invasion, foreign tissue invasion and eventually metastasis. Transplantation experiments utilizing the anterior chamber of the eye as an inoculation site showed that the tumors could not be transferred to normal animals during the stages of anaplastic cellular change but could be transferred to normal animals during the stage of foreign tissue invasion. In contrast to the failure of transfer to normal animals during stages prior to foreign tissue invasion, it was found that at such stages the developing tumors could be successfully transplanted to animals bearing spontaneous growths. This finding suggested that special factors were present in the spontaneous hosts but absent in normal animals and the nature of the endocrine changes constantly found in tumor bearing animals indicated that one of these factors might be an abnormal secretion of estrone. It was subsequently found that dependent tumors survived and grew in estrogenized animals, whereas early death of the transplants occurred in normal animals. The anterior chamber has also been used for the heterologous transplantation of mouse tumors and it has been found that in this species tumors undergo the same biologic phases of dependence and autonomy observed in the development of rabbit cancer. It has also been possible to transplant human tumors to lower species using this route of inoculation. The author concluded that the rabbit cancers are not simply local tissue diseases but represent local manifestations of a generalized constitutional disorder and that in the rabbit the primary neoplastic focus is not a cancer. Before becoming a cancer it must undergo a process of progressive evolutionary development. Development to cancer will not take place in normal animals but is dependent on a special constitutional status which may be evoked experimentally by the administration of estrogenic substances.

Treatment of Meningococcic Meningitis with Penicillin.—Meads and his associates report 9 cases of meningococcic meningitis, including 5 with meningococcemia, that were treated with the calcium salt of penicillin intrathecally and intramuscularly. All patients were started on both intramuscular and intraspinal penicillin immediately after the diagnosis was made. Initial intraspinal doses consisted of 10,000 to 20,000 units in 10 cc. of sterile isotonic solution of sodium chloride to replace a similar or larger volume of spinal fluid withdrawn. The number of intraspinal injections averaged about six, and the total amount of penicillin given intrathecally varied from 30,000 to 150,000 units, averaging about 75,000 units. Doses of 15,000 units were given intramuscularly every three hours in 7 cases and doses of 10,000 units every three hours in 2 cases. This therapy was continued until there were signs of clinical improvement. The duration of intramuscular therapy was two and a half to six and a half days. The total amount of penicillin given by this route ranged from 190,000 to 1,155,000 units, averaging almost 500,000 units. In 2 cases, because of poor clinical response and persistence of abnormal bacteriologic and spinal fluid chemical findings, penicillin was discontinued and sulfapyrazine was given, first parenterally and then orally in standard doses. In another case, because of persistent positive throat cultures after one week of penicillin therapy, a forty-eight hour course of sulfadiazine was given orally. The clinical and laboratory findings in this series suggest that the sulfonamides are

the drugs of choice rather than penicillin. If penicillin is used, careful observations should be made of the clinical course, the spinal fluid and nasopharyngeal flora and the spinal fluid chemistry. The clinical response to penicillin is slower than that to the sulfonamides, and one may eventually have to resort to the sulfonamides for cure. Calcium penicillin seems to be quite effective against group I meningococcus bacteremia. Strains of group I meningococci vary greatly in their susceptibility to penicillin. Strains from 5 patients in the present series resembled the relatively resistant ones of *Staphylococcus aureus* and *Streptococcus viridans*.

Meningococcal Infections.—Whitaker describes the clinical manifestations of meningococcal infections observed in a study of 116 cases at the U. S. Naval Hospital, Farragut, Idaho, during a thirteen month period. He divides infection resulting from the meningococcus into three phases: (1) the nasopharyngeal, (2) the septicemic or invasive, and (3) the meningial. Failure to recognize the signs and symptoms of the second (septicemic or invasive) phase has been a major factor in delayed treatment and the consequent high mortality. Fever, chills, headache, characteristic rash and arthralgia, in the presence of an epidemic, are sufficient to warrant the diagnosis of a meningococcal infection and to require early treatment while awaiting laboratory confirmation. The mortality rate seems to parallel the intensity and severity of the skin lesions. Evidence of adrenal damage with vascular failure must be carefully watched for, particularly in patients with extreme skin manifestations of the purpura fulminans or intense petechial types. Prognosis in such cases, while always grave, is not hopeless if early intensive treatment is instituted. A total mortality rate of 4.3 per cent occurred for all cases, treated or untreated, with a corrected rate of 1.72 per cent for cases treated for at least twenty-four hours. No evidence was obtained in this series of meningococcal infections to warrant further employment of antitoxin. Early diagnosis with prompt institution of chemotherapy, preferably by the parenteral route, maintaining a high concentration of the drug in the blood and spinal fluid, leads to rapid control of the infection and ultimate complete recovery in over 98 per cent of meningococcal infections.

Collapse of Intervertebral Disk Following Spinal Puncture.—Downing reports 2 cases in which collapse of the intervertebral disk followed operations in which a spinal anesthetic was employed. Both had the onset of back symptoms and disability shortly after operation, and in both subsequent x-ray studies showed partial collapse of the intervertebral disk between the third and fourth lumbar vertebrae. In the first

case the onset of early symptoms together with long delayed evidence of intervertebral disk collapse would indicate that the pain was due to extensive disk trauma rather than to the subsequent escape of nuclear substance. The resultant collapse of the disk was purely a later degenerative reaction precipitated by the original trauma; it was also manifested by productive osteoarthritic changes. It is likewise possible that the further productive bone changes were the result of a protective reaction from an altered mechanical condition producing abnormal stress and strain. This theory would also account for the chronicity of the symptoms and the failure to obtain relief by mechanical supportive treatment. In the second case the symptoms appeared later and not until the weight bearing had been reestablished. The collapse occurred in a period known to be not more than sixteen days. This is too short a period to be explained by degenerative changes and can be explained only by a rapid change in the intradisk pressure which would occur with escape of nuclear material. As it was known in this case the three unsuccessful attempts were made to obtain spinal fluid; the third and fourth lumbar interspace, three or more puncture of the annulus fibrosus in this region were possible. They could have occurred in its weakest portion, lateral to the posterior longitudinal ligament, and the damage produced could have been sufficient to allow the gradual escape of hydrostatic nuclear substance. The acutely flexed position of the spine when the puncture is made increases the danger of injury to the disk by increasing the intradisk pressure and directing the needle toward the intervertebral space. The needle should be angulated cephalad so that in case it is inserted too deeply it will strike the posterior surface of the superior vertebra. The need for the use of a sharp, fine caliber, short bevel needle and extremely careful technic is apparent.

Medicine in South Pacific. A. McMahon.—p. 348.
Tropical Disease: Etiology and Epidemiology. E. M. Bingham.—p. 355.

"Single Injection" Method in Diabetes Mellitus.—Peck states that at the Indianapolis City Hospital the principles of diabetic regulation have been altered. Instead of attempting to prescribe the individual's diet to suit the action of standardized insulin preparations, the opposite course was adopted, that of adjusting the insulin preparation to fit the individual circumstances. This is accomplished by prescribing three equal meals, no supplementary feedings, and the same laboratory criteria as previously required to establish control with insulin and protamine zinc insulin when given in separate doses. In order to provide a base line for comparison of methods, each case is first controlled as well as possible with separate doses of insulin and protamine zinc insulin. When this has been accomplished, the total dosage is given before breakfast each morning in the form of a suitable admixture in a single dose. If postprandial levels rise unduly, a greater proportion of insulin is needed in the mixture; if daytime reactions occur, less insulin is prescribed. Just as is the case when giving protamine zinc insulin separately, the dose of this component is governed by the blood sugar level as determined before breakfast. Usually patients who require less than 40 units daily have done well with 3:2 mixtures (3 parts of insulin to 2 parts of protamine zinc insulin); for those who need between 40 and 50 units daily the 2:1 mixture is usually suitable, while the more severe cases needing in excess of 50 to 60 units each day have required 3:1 or even rarely 4:1 combinations. Of more than 150 patients who have been observed under these conditions in the last two years, only 3 have been changed back to the separate injection method. Diabetic control has been at least equal to that accomplished with multiple injections and usually superior to it.

*Sonne Dysentery Carriers Treated with Succinylsulfathiazole. A. E. Brewer.—p. 471.
Bone Marrow Infusions for Infants. G. Behr.—p. 472.

Hazards of Hypertherm Treatment.—Wallace and Bushby investigated changes occurring in patients undergoing hypertherm treatment to ascertain whether chemotherapy increases the risks and to discover prophylactic or therapeutic means of eliminating or minimizing the danger inherent in the treatment. They report clinical observations on 254 cases undergoing hypertherm treatment at 106.6 F. for eight hours. Of these, 37 were the subject of a detailed clinical, hematologic and biochemical investigation. The most constant and prominent features were the development of anoxia and of bilirubinemia progressing to definite clinical jaundice in 37 cases. Hippuric acid tests for liver function showed a considerable reduction in this function. Patients with jaundice should be treated as if they had hepatitis and should be kept warm in bed for at least three days or until the jaundice clears. Continuous oxygen and carbon dioxide therapy lessens, though it does not abolish, the anoxia. It appears to prevent circulatory collapse. Vomiting was less frequent after its introduction. Circulatory collapse is a failure of the vasomotor and respiratory centers and is not due to a reduction in the volume of the circulating blood or to myocardial failure. The use of morphine is contraindicated. Hypertherm treatment causes a transient polymorphonuclear leukocytosis and a transient hemodilution. There is a small transient rise in nonprotein nitrogen and a tendency for plasma chlorides and urinary chlorides to fall. The treatment has considerable dangers. The duration must be decided by the medical officer observing each case, but the following are suggested as indications for terminating treatment immediately: (1) fall of systolic blood pressure below 100 mm. of mercury, (2) disorientation, (3) pulse rate persistently over 160 per minute, (4) respiratory rate persistently over 50 per minute, (5) temperature of 107 F. for a quarter of an hour, (6) restlessness and violence, (7) coma, (8) pallor superimposed on cyanosis, (9) intolerance on the part of the patient, the restlessness of an intolerant patient adding greatly to the risks inherent in the treatment, (10) persistent vomiting. Catarrhal infection and nasal obstruction should be regarded as contraindications to treatment. The patient should be examined preparatory to the hypertherm treatment so as to exclude those with cardiovascular, respiratory, renal or hepatic disease. The treatment should be carefully explained beforehand to prepare the patient for his physical and mental ordeal. Oxygen and carbon dioxide should be given for at least an hour after treatment or until color improves. Premedication with 6 Gm. of sulfathiazole does not increase the hazards of hypertherm treatment.

Neurologic Complications of Serum and Vaccine Therapy.—Hughes reports 3 cases of serum neuritis that were seen at military hospitals in England within a year. The first 2 were of the radicular type. In the third case disseminated sclerosis was at first thought of, because the author was not aware that the neurologic lesion could result from vaccine injection. On reconsideration, however, serum neuritis of the central type seemed a more likely explanation and in view of the time relationship more probably the result of tetanus toxoid rather than of T. A. B. vaccine. On investigating the records of all cases of peripheral neuritis admitted to the hospital during the past two years, 3 further cases of serum neuritis were discovered. Two of these were again of the radicular type. The other case showed wrist drop due to a right musculospinal palsy. This appeared ten days after an intravenous injection of T. A. B. vaccine. The similarity between the radicular, neuritic and poly-

neuritic forms of serum neuritis and the types of "virus" neuritis is striking and suggests that for the time being these two types of neuritis should be regarded as being of the same group. It seems possible that "serum" and "virus" neuritis will prove to have the same cause.

Sonne Dysentery Treated with Sulfaguanidine.—Osborn and Jones review observations on 71 cases of dysentery which recently occurred in a naval officers' training establishment accommodating about 250 people. On the first day of the outbreak there were 9 cases, on the second day 14 more and on the third day 20; in the next two weeks there were 21 and 7 respectively. The diarrhea stools, which contained mucus but no blood, were preceded by two to four hours' fever and malaise. The diarrhea was severe in the early cases, and these required treatment in bed for two days. The symptoms never lasted more than two or three days, but varying intervals elapsed before negative stool cultures were obtained. The diagnosis was made in all cases from stool cultures. Forty-seven of the patients were at first treated with small doses and later with larger doses. These required an average of seven to eight days to become free from infection. Another 16 treated from the onset with the larger doses became free from infection in an average of four days. The authors conclude that sulfaguanidine is a satisfactory drug for treating Sonne dysentery but that it should be used in larger doses than are at present recommended, since smaller doses tend to encourage ambulant cases and possible carriers.

Dysentery Carriers Treated with Succinylsulfathiazole.—In an investigation carried out after an outbreak of Sonne dysentery in an army unit, Brewer found that in 16 of 32 patients the causal organism was still recoverable from the stools one to three weeks after all symptoms had ceased and the patients were well again. This is a potential carrier rate of 50 per cent. Nine of the 16 patients had been treated with sulfaguanidine and the remaining 7 had no treatment other than rest in bed, restricted diet and bismuth and soda and salts. Times taken for clinical recovery in the two groups were the same and gave an average of three days, so that sulfaguanidine does not appear to influence the course of the disease. The 16 patients in whom culture of fecal specimens on desoxycholate citrate agar yielded positive results after they were well again were given 44 Gm. of succinylsulfathiazole over five days. This treatment cleared all but 1 patient, who required two such courses. In vitro experiments showed that succinylsulfathiazole has a bacteriostatic effect on *Bacterium sonnei* directly proportional to the amount of drug present and inversely proportional to the number of bacilli present. Sulfaguanidine in vitro does not have this bacteriostatic effect.

Revista de la Asoc. Méd. Argentina, Buenos Aires
58:547-608 (July 30) 1944. Partial Index

- *Local Sulfonamide Therapy and Repair of Tissues. A. Fernández Saralegui and A. A. Villanueva.—p. 563.

Effects of Local Sulfonamides on Tissues.—Fernández Saralegui and Villanueva observed that sulfonamides applied locally to chronic ulcers and wounds arrest healing, which can be stimulated if the sulfonamide is mixed with allantoin. The authors used a powder consisting of equal parts of sulfanilamide and sulfathiazole and an ointment which contained 2 per cent allantoin, 7 per cent sulfanilamide, 40 per cent cod liver oil and a greaseless base in sufficient quantity to give the ointment the desired consistency. Sulfanilamide when applied locally to wounds and chronic ulcers has a selective inhibitory effect on the various types of bacteria. The effect of the drug depends on the time during which it is maintained in proper concentration during its contact with the tissues. The concentration of the drug in the wound or ulcer depends on the type of sulfonamide used, since the solubility of the drug varies with the various types of the drug. The bacteriostatic effect of sulfanilamide is favorably modified by phagocytosis and by the elimination of inhibitory substances from the wound or ulcer. The allantoin and sulfonamide mixture (or ointment) stimulates phagocytosis, accelerates the elimination of substances which inhibit healing, prevents the harmful effect of sulfanilamide and stimulates cell proliferation and the formation of new tissue.

Book Notices

Principles and Practice of Surgery. By W. Wayne Babcock, M.D., Acting Consultant, Philadelphia General Hospital. With the collaboration of Members of the Faculty of Temple University. Cloth. Price, \$12. Pp. 1,331, with 1,149 illustrations. Philadelphia: Lea & Febiger, 1944.

As the author states in the preface, he made the attempt to cover in one volume not only common but also rare surgical conditions occurring throughout the world. This ambitious undertaking has been accomplished in an admirable manner by the author and his thirty-seven collaborators of the Faculty of Temple University. The second edition of the author's "Text-book of Surgery" has been remodeled by these thirty-seven architects in such a manner that the new, imposing, streamlined structure incorporates latest advances in surgery, including experiences gained in the present war. Shortcomings of this type of textbook, such as overlapping of subjects or contradictory opinions, have been avoided by the fact that the majority of co-authors work together at Temple University. It is amazing how much valuable information has been squeezed into one volume. The style of the book is simple, it is easily readable, the text is compact and to the point, illustrations are numerous and adequate, the color plates are splendid. A cursory perusal revealed a few omissions. For instance, on page 36 the necessity of daily determinations of prothrombin time while using dicumarol has not been mentioned. Pectin deserves a place among drugs used in the treatment of shock (p. 55). Mediastinal emphysema should be added to the list of indications for operations in chest injuries (p. 69). Nylon and tantalum should be included in the list of suture materials. The description of a negative and double positive Trendelenburg test on page 494 will raise in the minds of the students the question "What is a single positive Trendelenburg test?" Such minor omissions do not detract from the value of the book, which is so preeminent in the field that it can be most heartily recommended not only to students but to general surgeons as well.

Bailey's Text-Book of Histology. Revised by Philip E. Smith, Ph.D., Professor of Anatomy, College of Physicians and Surgeons, Columbia University, New York, and Wilfred M. Copenhaver, Ph.D., Associate Professor of Anatomy, College of Physicians and Surgeons, Columbia University. With the assistance of Aura E. Severinghaus, Ph.D., Associate Professor of Anatomy, College of Physicians and Surgeons, Columbia University, and Charles M. Goss, M.D., Professor of Anatomy, University of Alabama Medical School. Eleventh edition. Cloth. Price, \$6. Pp. 786, with 470 illustrations. Baltimore: William Wood & Company, 1944.

Eleven editions and three reprintings are ample proof of the fact that this book fulfils the requirements of a good textbook. The descriptions are clear and accurate, and enough functional correlation is included to make the structures come to life for the student. Problems and controversial material are presented and discussed in a stimulating manner. The references to the literature at the end of each chapter are well selected. This edition has been improved by the introduction of many new and mostly original illustrations. Sections on the placenta and carotid and aortic bodies have been added. The chapter on the pineal body is rewritten and extended, and several minor changes in the text have brought the material up to date. On the whole the book has retained its previous character and will continue to serve as an excellent textbook for medical students.

Tratado sobre las rickettsias y las fiebres exantemáticas, el tífus altiplánico. Por el Dr. Félix Veintemillas, director del Instituto N. de bacteriología y catédrico de la Facultad de medicina de La Paz. Publicado por el Ministerio de higiene y salubridad ante la recomendación del segundo Congreso médico nacional. Paper. Pp. 479, with illustrations. La Paz: Escuela Tip. Salesiana, 1944.

This is a book giving a complete picture of the diseases due to the rickettsias. It is divided into three chapters. The first treats of the rickettsias in general as to the nomenclature, origin, nature, morphology, staining, resistance, growth, mediums, susceptible animals and the biologic characteristics of the organisms of the various diseases designated rickettsia. The rickettsias are classified with their arthropod vectors. The second chapter gives a lucid, comprehensive study of the clinical aspects of the fiebres exantemáticas, including an interesting history of each disease. The epidemiology, histology, geographic distribution,

treatment, prophylaxis and immunization are reviewed in a complete manner. In the third chapter the author deals in detail with the extremely metamorphic study of his original observations of "tífus altiplánico." (The term "altiplánico" refers to a specific region of southwestern Bolivia encompassing the states of Potosi and Oruro having an elevation of 9,000 to 13,000 feet.) The author first noted the disease as a student and diagnosed it as typhoid, then as paratyphoid. Finally, following his experiences and study in Germany during the first world war he suspected that the disease was in truth epidemic typhus or a typhus-like disease. He returned to La Paz to prove that the disease of his medical school thesis was epidemic typhus. The clinical aspects of "tífus altiplánico" and the diagnosis, pathology and experimentation with the virus in vivo are reviewed in detail. Finally treatment and prophylaxis are detailed.

Gynecology and Gynecologic Nursing. By Norman F. Miller, M.D., Professor of Obstetrics and Gynecology, University of Michigan Medical School, Ann Arbor, and Virginia Bryant, R.N. With a chapter on The Gynecology Operating Room by Molly Kowal, R.N., Operating Room Supervisor, University of Michigan Medical School. Cloth. Price, \$2.75. Pp. 378, with 227 illustrations. Philadelphia & London: W. B. Saunders Company, 1944.

This textbook for nurses is designed to provide a thorough background in gynecology for the undergraduate and graduate student. The material is assembled in a logical manner so that the nurse adds to her fund of information systematically. A complete description of the anatomy of the pelvic organs, their physiologic functions and the common perversions of these functions precedes a discussion of pathologic conditions. The major emphasis is placed on the nature and the course of the disease and little on therapy. A chapter on gynecologic nursing procedures covers minutely the preparation and the armamentarium necessary for all gynecologic operations. The various steps of these operations are listed in detail. Although these descriptions refer to the nursing technic at the University of Michigan Hospital, they are fundamentally sound and represent well accepted procedures in use in most gynecologic services. Minor office and clinic problems are likewise described carefully and in great detail. The text is profusely illustrated by pen and ink drawings skilfully prepared to enhance the pedagogic value of the descriptive material. The artists deserve special commendation for their work. This gynecologic textbook is a distinct addition to nursing books in our special field. It follows the recent trend of sharing our teaching responsibility to nurses between the physician and the nurse. The senior author is a gynecologist and a teacher of note. Physicians and medical students have profited and enjoyed his interesting, lucid lectures and writings for years. This nursing textbook has given him an opportunity to extend the scope of his teaching to nurses.

Klinika malyarii. [By] Prof. L. M. Tarceev. [Clinical Aspects of Malaria.] Paper. Pp. 299, with 37 illustrations. Moskva: Narukomzdrav SSSR, Gosudarstvennoe izdatelstvo meditsinskoy literatury "Medgiz," 1943.

The extensive monograph by Professor Tarceev, chief of the clinical division of the Central Malaria Institute in Moscow, is devoted to a systematic discussion of the pathogenesis, symptomatology, diagnosis and course of malaria. Considerations of the parasite, the vector, the epidemiology and the epidemiologic methods of combating the disease are not included. The monograph is devoted exclusively to the discussion of the purely clinical questions, particularly those pertaining to the involvement of the various organs and the many complications of malaria. Correlation of the symptoms with the pathogenesis, immunity and the host parasite relationship is stressed. The author draws for illustrative cases on the extensive material of the Central Malarial Institute in Moscow. The various chapters deal with the general characteristics of the malarial infection, the basic triad spleen, liver and blood, the lesions of the various systems, special types of the malarial infection, diagnosis and prognosis, and the prophylaxis and treatment of the disease. Bibliographic references are limited to the more important recent contributions in the fields of parasitology, entomology and epidemiology of malaria. The monograph makes interesting reading and will undoubtedly prove of great practical value in the combat waged by the Soviet Union against this important disease.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

SURGICAL REPAIR OF INGUINAL HERNIA

To the Editor:—Has there been any recent advance in the surgical technic of repair of inguinal hernia? N. I. Ardan, M.D., Niagara Falls, N. Y.

ANSWER.—The principles of Bassini and Halsted are still sound. It is generally accepted that the basis of repair is high ligation of the hernial sac in indirect hernia and careful repair of the transversalis fascia in a direct hernia. A number of surgeons have expressed a preference for nonabsorbable sutures, such as silk or cotton. McVay and Anson (McVay, C. B., and Anson, B. J.: *A Fundamental Error in Current Methods of Inguinal Herniorrhaphy, Surg., Gynec. & Obst.* 74:746 [March] 1942) recommended that the inguinal layers be sutured to Cooper's ligament and not to the inguinal ligament (Poupart's ligament in old terminology). They point out that the inguinal ligament is neither the normal insertion of the inguinal layers nor a suitable substitute for such an attachment; on the contrary, the superior pubic or Cooper's ligament, which is the normal insertion, is readily accessible, intrinsically strong and directly fixed to the bone. Harkins and Swenson (Harkins, H. M., and Swenson, S. A., Jr.: *A Cooper's Ligament Herniotomy, S. Clin. North America* 23:1279 [Oct.] 1943) used this technic in the repair of 322 groin hernias, and they feel that their results justify the theoretical advantages of this procedure. The MacArthur, Gallie and LeMesurier use of living fascial strips is not new and cannot be classified as an advance. Bost (Bost, T. C.: *A Further Improved Technique for the Cure of Inguinal Hernia, North Carolina M. J.* 3:109 [March] 1942) first traumatized the tissues to be sutured by cauterization and claims to have obtained in dogs a much firmer union of muscle to fascia suture. A follow-up of 381 operative cases clinically for a year or more revealed only 4 recurrences—a very low incidence indeed. A single report, however, cannot be regarded as definite solution of the problem of cure of inguinal hernia.

SALPINGOSTOMY AND TUBAL IMPLANTATION

To the Editor:—A woman aged 29, at present in good general health, had a pelvic infection seven years ago following an induced abortion. She has not been pregnant since that time but has had a profuse menstrual flow and hot flashes, accompanied by palpitations of the heart. On May 27, 1944 an emergency appendectomy was performed, at which time were discovered many adhesions in the pelvis, a bilateral salpinx and a small simple cyst on the right ovary; the left ovary was adherent to the posterior aspect of the uterus. With some difficulty the tubes were removed, the cyst on the right ovary dissected out, the left ovary freed from its adhesions and the appendix removed. She made an uneventful post-operative recovery and has done well except for an apparent need for estrogenic substance. She wants to have a child. She has heard of an operation whereby a small piece of ovary is inserted into a wedge of uterus with the possibility that an egg cell might escape into the uterine canal, resulting in pregnancy. It seems to me that the chance of a pregnancy resulting is hardly worth the surgical risk. Are there statistics relative to the success of such a procedure, and what is the current opinion as to its value? Can any other procedure be suggested? David Hoehn, M.D., Palmer, Alaska.

ANSWER.—In an article entitled "Evaluation of Salpingostomy and Tubal Implantation for the Treatment of Sterility" J. P. Greenhill (*Am. J. Obst. & Gynec.* 33:39 [Jan.] 1937) says, concerning ovarian implantation:

"Some gynecologists who are opposed to tubal implantation remove the entire tube with the uterine corner and implant a portion of an ovary on the exposed portion of the uterus. A few gynecologists transplant the ovary into the uterine cavity. Von Graff collected 66 cases in which a graft of ovarian tissue was placed on a uterine horn or on a tubal stump. He reported 14 pregnancies (21.2 per cent) following these operations. However, since only 5 of these pregnancies went to term, only 7.6 per cent of the operations, or 1 in 13.2 operations, resulted in a full term baby. Among the remaining 9 gestations there were 6 abortions and 1 ectopic pregnancy. The outcome in 2 cases was unknown. In Von Graff's collected series of 41 cases in which an ovary was transplanted into the uterine cavity, only 3 pregnancies (7.5 per cent) resulted, of which 1 went to term (2.4 per cent) and the other 2 ended in abortion. Reiprich collected 200 ovarian transplants of all types and

reported only 5 pregnancies (2.5 per cent) following these operations. Estes followed up 27 out of 88 patients on whom he had performed his ovarian transplantation operation and found that pregnancy had occurred in 4 of them (15 per cent). In a later article Estes reported that in a series of 50 patients whose case records were complete only 4 became pregnant (8 per cent). Two of these women had abortions and 2 had full term babies.

"Novak states (personal communication) that 4 pregnancies resulted after the six Estes operations he had performed. Because of economic conditions 3 of these women had induced abortions, but the fourth patient had a spontaneous abortion.

"Some of the complications which I have described as having followed plastic operations on the tubes have also occurred after ovarian transplantation. Thus R. E. Watkins performed an ovarian transplantation and subsequently had to do another operation to remove the transplanted ovary, which had grown to be a cystic mass 9 cm. in diameter and which proved to be a chocolate cyst. Wier reported a death following an ovarian transplantation. This woman became pregnant following an ovarian graft, but her uterus ruptured during labor. Autopsy revealed that the rupture had occurred at the site of the ovarian transplantation.

"In a personal communication Mathieu described a case in which he removed a fallopian tube, made an opening in the cornu and sutured an ovary into the uterus at this point. The patient became pregnant. Fearing that a rupture of the uterus might take place, Mathieu performed a cesarean section and found the transplanted ovary in the same position but flattened out like a pancake and about 8 cm. in diameter. He was able to insert five fingers through this thin ovary into the uterine cavity. Hence his fears concerning a rupture of the uterus were well substantiated."

Unfortunately, since this patient does not have even part of one tube, no surgical operation other than ovarian implantation can be done, and this is not worth while in view of the condition of the patient's pelvis.

SALT TOLERANCE TESTS FOR PITUITARY DYSFUNCTION

To the Editor:—Kindly send me the exact technic and the interpretation of the salt tolerance test for glandular dysfunction; in particular, pituitary dysfunction. M.D., New York.

ANSWER.—Salt tolerance tests for pituitary dysfunction are difficult to interpret in precise terms. Cantarow's studies (*Science* 90:375 [Oct. 20] 1939) involved administration of 10 Gm. of sodium chloride (in capsules) with the morning meal and again with the evening meal for a period of two days. The diet contained approximately 1.6 Gm. of sodium chloride and 4.0 Gm. of potassium; intake of fluid was fixed at 20 cc. per kilogram of body weight daily. On the third day the bladder was emptied at 8 a. m. and urine was collected for the subsequent period of four hours. During this time 5 cc. of fluid per kilogram of body weight was given before 11 a. m. The concentrations of chloride ion (not NaCl) in the four hour specimens of urine were, in 3 subjects with Cushing's syndrome and 1 with hirsutism, 0.193, 0.243, 0.357 and 0.179 per cent chloride respectively and the volumes were 475, 450, 500 and 535 cc. In 12 other subjects who had miscellaneous disorders, with no evidence of endocrine dysfunction, these concentrations of chloride ranged from 0.462 to 1.265 per cent (mean 0.642) and the urine volumes from 680 to 1,170 cc. The author suggested that "this test may prove to be of value in detecting states of hypercortico-adrenalism."

Goldzieher (*Clinics* 1:1069 [Feb.] 1943) described a somewhat simpler procedure. Intake of food and water is kept constant for two days and, on the morning of the second day, 10 Gm. of sodium chloride and 250 cc. of water are given in addition. Urine is collected for each of the twenty-four hour periods, and the quantity of sodium chloride in each specimen is estimated. This author stated that retention of part or all of the test dose of salt, along with water, frequently is observed in association with menstrual disorders, obesity and hirsutism and in subjects with signs of hypopituitarism such as low basal metabolic rate, low specific dynamic action of proteins, relative lymphocytosis, low fasting blood sugar and increased uric acid.

Stephens (*Am. J. M. Sc.* 199:67 [Jan.] 1940) has applied the salt depletion test of Cutler, Power and Wilder (*THE JOURNAL*, July 9, 1938, p. 117) for adrenal cortex insufficiency to subjects with hypopituitarism. In this procedure the subject is given for two days a diet containing about 1.5 Gm. of sodium chloride and 4.0 Gm. of potassium daily. On the first day water as desired is allowed and additional potassium in the form of 42 mg. of potassium citrate per pound of body weight is given in the afternoon. On the second day the dose of potassium citrate is repeated in the morning and intake of fluid is adjusted to 40 cc.

per kilogram for the day. On the morning of the third day breakfast is omitted, the bladder is emptied at 8 a. m. and thereafter all urine voided up to 12 noon is saved. In Addison's disease the concentration of chloride in this four hour specimen was found to range from 382 to 593 mg. per hundred cubic centimeters (as NaCl), mean, 489, while Stephens found that in 6 of 7 cases of clinical hypopituitarism the concentration of chloride in the four hour specimen ranged from 427 to 690 mg. of sodium chloride per hundred cubic centimeters. In 4 of these 6 patients symptoms suggesting those of Addisonian crisis developed. Further reference to the use of the salt depletion procedure in the study of hypopituitary conditions was made by Stephens (*J. Clin. Endocrinol.* 1:109 [Feb.] 1941) and by Wohl and Larson (*M. Clin. North America* 26:1657 [Nov.] 1942). Neither the salt tolerance nor the salt depletion test should be applied in the presence of frank renal disease.

POSSIBLE TREATMENT RESISTANT SYPHILIS

To the Editor:—A man aged 27 came into my office recently and gave me the following history: He developed a lesion on his penis on March 1, 1943, which was diagnosed as a primary lesion by dark field examination. He began taking treatments for syphilis at once. He took arsenic injections in the vein once a week for three months. At this time he developed a rash which was thought to be due to the injections. The injections were stopped and treatment was given by mouth for about two weeks. He was also given a bismuth compound intramuscularly once a week along with the oral medications. However, the rash persisted and was diagnosed as psoriasis. On or about June 1, 1943 he went to another doctor. He continued treatment for another three months. He took an arsenic injection in the arm and a bismuth injection in the hip once a week. On Sept. 10, 1943 he was referred to a specialist, who also diagnosed the case as syphilis. He took the same treatment as he had been taking before for another three months. The rash, however, failed to clear up. In December 1943 he was referred to another specialist. A biopsy of the skin lesions was taken and diagnosed as psoriasiform syphilis. The laboratory reports on blood tests continued to be positive, and so stronger treatment was advised. He then took three injections a week, two arsenic and one bismuth for a month and then two bismuth and one arsenic for six months. Throughout this period of treatment a Wassermann test was performed every three months and never once showed negative. He came to me after having discontinued treatment for two months. Three tests were performed, and all three were negative. A provocative Wassermann was run, and the report of this was negative. One week later four Wassermann tests were done on consecutive days and all were positive. Would you consider this patient as Wassermann fast? Has he had adequate treatment or would further treatment be advised? He has not had a colloidal gold test. Do you think this should be done? He has no symptoms of cerebrospinal syphilis and his reflexes are normal.

M.D., Texas.

ANSWER.—The history of this patient is so inadequate that it is difficult to draw any conclusions. It is quite possible that the patient had a psoriasiform resistant type of syphilis. How much treatment he has had, however, is difficult to make out from the description, and apparently the patient has never had a spinal fluid examination or a general physical examination. A serologic test alone is not enough to allow definite conclusions. As a rule, when a patient is receiving treatment with arsenicals and bismuth compounds it is generally felt that he may be considered cured if he has been on continuous alternating courses of treatment with arsenicals and bismuth for a period of one year after the serologic reaction has become negative and provided physical examination and fluoroscopic examination of the cardiovascular system and lumbar puncture are entirely negative.

LARVA MIGRANS

To the Editor:—What is the latest treatment for larva migrans (creeping eruption)? We see many severe cases at this base and find the usual remedies, such as ethyl chloride sprays, to be only moderately satisfactory. Are there any drugs that may be given by injection which will eradicate this condition?

Lieutenant (MC), U.S.N.R.

ANSWER.—In a single case, an apparent cure of creeping eruption was obtained by injections of sodium antimony bisulfate (fuadin). A 6.3 per cent solution was used, of which 2 cc. was injected intramuscularly once daily for five days. After a rest period of one week the series of injections was once repeated as given before (Smith, D. C.: Treatment of Creeping Eruption with Sodium Antimony Bisulfate (Fuadin) (*THE JOURNAL*, Nov. 13, 1943, p. 694). Others reported the effects of injections of fuadin on creeping eruption as a failure to cure in 1 case (Blank, Henry, *ibid.*, Dec. 11, 1943, p. 989), a successful cure in a single case (Rubin, S. S., *ibid.*, March 4, 1944, p. 668) and successful cures in 6 cases (Wilson, J. F.: *J. Florida M. A.* 30:425 [April] 1944).

An application which one observer has found useful in allaying the pruritus attending the disease consists of boric acid 4.5 parts, thymol 0.1, methyl salicylate 0.2, oil of peppermint 0.1, oil of camphor 2, oil of eucalyptus 2, kaolin 53.5 and glycerin 37.6.

CHRONIC NONCALCULOUS CHOLECYSTITIS

To the Editor:—In the therapy of chronic infectious diseases of the gallbladder has any one investigated the efficacy of the dosage of desoxycholic acid (1½ grain tablet) and the dehydrocholic acid (3¾ grain tablet) on the function of the gallbladder? In other words, will 3¾ grains or 7½ grains of Retachol after one meal increase production of bile 144 per cent? How much fat will 1½ grains of desoxycholic acid emulsify? What would be rational therapy in hypofunctioning cholecystic disease?

Clifford W. Atherton, M.D., Peoria, Ill.

ANSWER.—The question implies the existence of abdominal distress secondary to chronic noncalculous cholecystitis or hypofunction of the gallbladder. Both of these hypotheses are probably incorrect. Cholelithiasis and acute cholecystitis are, of course, definite pathologic and clinical entities. Chronic cholecystitis manifested on pathologic examination by round cell infiltration of the gallbladder wall is often found in association with cholelithiasis. The symptoms attributed to such chronic cholecystitis may be found in gallbladders showing the same signs of inflammation without stones but are also present frequently in cases in which the gallbladder is normal. In the noncalculous gallbladder there is no correlation between the pathologic findings at operation and the symptoms, nor is relief of these symptoms consistently observed following cholecystectomy. Furthermore, the symptoms are usually relieved when treated without reference to the gallbladder. These observations support the view that the symptoms are not due to local organic disease but are part of disturbed function not confined to the biliary tract but present in the alimentary tract as a whole.

Treatment is satisfactorily accomplished by means of a non-irritating diet, antispasmodics, sedatives and supportive psychotherapy. Bile salts are contraindicated because their laxative and irritating effect only aggravates the altered function of the alimentary tract already present. This concept of so-called gallbladder dyspepsia should not be confused with cholelithiasis producing biliary colic and treated only by cholecystectomy. The two conditions may be superimposed, but no definite evidence of their relation to each other has been irrefutably established.

LOSS OF LIBIDO AFTER UNILATERAL ORCHIECTOMY

To the Editor:—What is the possibility of loss of libido occurring in a young man following orchietomy and irradiation for teratoma? What therapy could be instituted if loss of libido occurred?

M.D., New Hampshire.

ANSWER.—Clinical experience shows that most men who have had a unilateral orchietomy followed by irradiation for teratoma of the testis do not have loss of libido. However, sterility may occur and a temporary complete or partial loss of erections may develop. If there has been loss of libido without evidence of metastasis, a blood count should be made, and if anemia is present this might be the cause. There is no specific treatment for loss of libido. It is doubtful that male sex hormone should be used or would be of any benefit to such a patient.

ABSORPTION OF YELLOW MERCURIC OXIDE FROM MUCOUS MEMBRANES

To the Editor:—What, if any, untoward effect could be expected from the continued use over a long period of time of 1 per cent yellow mercuric oxide on the mucous membrane of the nasal passages where, say, 3 drams was used over a period of a year. To me this seems a small amount of mercury, but I have been asked this question.

B. Wright Shelton, M.D., Miami, Okla.

ANSWER.—There would not be the least untoward effect from the use of a 1 per cent yellow mercuric oxide on the mucous membrane of the nasal passages where 3 drams (11.5 Gm.) was used over a period of a year. There would be little or no absorption from that amount.

HAIR DYES

To the Editor:—I have read in your column various comments concerning hair dyes and have been interested especially in the advice against their use. I am aware that allergy is one of the objections, but I should like to know whether there is any reason to believe that prolonged use will eventually destroy the hair. Would there be any difference between dyeing the whole head and touching up parts of the hair?

M.D., New York.

ANSWER.—There is no evidence that prolonged use of dyes will eventually destroy hair. As far as destroying hair is concerned there should be no difference between dyeing the whole head and touching up part of the scalp.

THE TREATMENT OF SUBACUTE BACTERIAL ENDOCARDITIS WITH PENICILLIN

RESULTS IN TWENTY CASES

MARTIN HENRY DAWSON, M.D.

AND

THOMAS H. HUNTER, M.D.

NEW YORK

The present report deals with the use of penicillin in the treatment of 20 cases of subacute bacterial endocarditis. The cases are divided chronologically into 2 groups: (1) a preliminary group of 5 cases treated in the latter part of 1942 and in 1943 and (2) a group of 15 cases treated between January and September 1944. In all instances the infecting organism was a streptococcus of either the viridans or indifferent variety.

PART I: CASES TREATED IN 1942 AND 1943

Cases selected for preliminary clinical trial showed the following characteristics: (a) The infection was of relatively short duration, (b) the patients' cardiac status and general condition were comparatively good and (c) the infecting organism was sensitive to penicillin in vitro. All 5 cases represented classic examples of the disease, and the diagnosis was established by several positive blood cultures on each patient. The underlying cardiac disease was rheumatic in all instances. In this preliminary group the therapeutic program was seriously handicapped by the limited amount of penicillin available. At no time was there assurance that continued supplies would be forthcoming, and from time to time it became necessary to alter the dosage schedules according to the amount of drug on hand or even to discontinue therapy entirely until further supplies were received. A preliminary report on these cases has already been presented.¹

Brief synopses of the 5 cases follow:

CASE 1.—H. H., a woman aged 27, known to have had "endocarditis" at the age of 10, was admitted to the Presbyterian Hospital on Oct. 17, 1942, with a history of weakness, loss of weight, palpitation and low grade temperature of two months' duration. Three months previously some teeth had been extracted, and one month later the tips of several fingers became painful. Examination showed several petechiae in the mouth, a moderately enlarged heart with aortic and mitral systolic and

diastolic murmurs, and a palpable spleen. Three blood cultures were positive for *Streptococcus viridans* with 60 to 80 colonies per cubic centimeter. Serologically the organism was a member of group F (Lancefield) and in vitro was one half as sensitive to penicillin as the standard strain of hemolytic streptococcus.²

Penicillin, 10,000 units every three hours intravenously, was started on October 23 and continued for six days. During this time the blood culture became sterile but the temperature remained elevated, and on November 3 the patient passed an embolus to the right femoral artery. Penicillin in the same dosage was resumed on November 5 and continued for five days. Blood cultures on November 10 and November 14 were positive. Penicillin was again started on November 17 and continued for a period of six days. Following this third course, blood cultures became negative but, because of the persistence of a low grade fever, therapy was resumed as a precautionary measure. From December 7 to December 12, 5,000 units was administered every three hours intravenously. During this time the temperature rose slightly and petechiae appeared on the finger tips. In spite of these signs, blood cultures were sterile and continued to remain so. The total amount of penicillin administered was 1,420,000 units.

Although the bacteremia appeared to have been satisfactorily controlled, the patient developed a number of serious complications during the ensuing weeks. On December 23 signs of an inflammatory pelvic mass appeared and she was placed on sulfadiazine. The response was apparently satisfactory and she was allowed to go home. On Feb. 5, 1943 she was readmitted because of recurrence of the inflammatory mass, and exploratory celiotomy was performed. At operation an infected ovarian cyst was found, and cultures revealed *Str. viridans*, group F, apparently the same organism which had been present in the blood stream. Since pelvic examination at the time of the first admission had revealed no abnormality, it was assumed that the infection resulted from a septic embolus. The patient's general condition did not permit extensive surgery, and hence the cyst was marsupialized. While convalescing from the operation, she developed an acute iridocyclitis and endophthalmitis which ultimately resulted in complete loss of vision in the left eye. Because of the development of draining sinuses and recurring abscesses of the abdominal wall, the subsequent course was protracted. Throughout this period, however, nineteen blood cultures were taken and all were sterile. Finally on April 6, 1944 she was readmitted for radical pelvic surgery. During this admission penicillin was administered prophylactically. Convalescence was uneventful and on April 30 she was discharged. Since then her course has been eminently satisfactory; she has gained 25 pounds (11.4 Kg.), is strong and healthy and leads a normal, active life. Blood cultures have consistently remained sterile.

CASE 2.—H. L., a woman aged 25, known to have had rheumatic fever in childhood, with subsequent rheumatic heart disease, was admitted Feb. 12, 1943 with a ten weeks history of fever and malaise. Examination revealed mitral stenosis, petechiae, clubbed fingers and a palpable spleen. Blood cultures were positive for *Str. viridans*, 68 colonies per cubic centimeter. The infecting strain belonged serologically to group H and was

Owing to lack of space, this article has been abbreviated for publication in THE JOURNAL. The complete article appears in the authors' reprints.

From the Edward Daniels Faulkner Arthritis Clinic of the Presbyterian Hospital and the Department of Medicine, Columbia University College of Physicians and Surgeons.

The penicillin was provided by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for clinical investigations recommended by the Committee on Chemotherapeutics and Other Agents of the National Research Council.

2. Dawson, M. H.; Hobby, G. L., and Lipman, M. O.: Penicillin Sensitivity of Strains of Nonhemolytic Streptococci Isolated from Cases of Subacute Bacterial Endocarditis, Proc. Soc. Exper. Biol. & Med. 56: 101 (June) 1944.

from one half to one fourth as sensitive to penicillin as the standard strain of hemolytic streptococcus.

On February 17 penicillin was started, 10,000 units every three hours intramuscularly for two days and then 5,000 units every three hours for four days. Although the temperature became normal within twenty-four hours and remained so on succeeding days, blood culture on February 23 showed 6 colonies per cubic centimeter. On February 26 penicillin was resumed, 5,000 units every three hours intramuscularly, and was continued for five days. The temperature again became normal, but blood culture on March 4 showed 24 colonies per cubic centimeter. On March 8 penicillin was started again, 10,000 units every three hours intramuscularly, and was continued for six days. Once more the clinical response was favorable, but blood cultures continued to be positive. After a total of 975,000 units had been given, penicillin therapy was discontinued because of our inability to obtain a further supply of the drug. She was then placed on sulfadiazine, which appeared to keep the infection in check, although blood cultures continued positive. She was discharged after six and one-half weeks' hospitalization and followed in the outpatient department for the next eleven months. The subsequent course of events is described in the second part of this communication.

CASE 3.—F. R., a woman aged 40, first seen on April 1, 1943, gave a classic history of subacute bacterial endocarditis of three months' duration. Examination showed the presence of rheumatic heart disease. Numerous embolic phenomena had occurred, and blood cultures were repeatedly positive for *Str. viridans*, 60 colonies per cubic centimeter. The infecting organism belonged serologically to group F and was from one half to one fourth as sensitive to penicillin as the standard strain of hemolytic streptococcus. The patient had previously been treated with massive doses of sulfadiazine without appreciable effect.

After the administration of 10,000 units of penicillin every three hours intramuscularly for five days, the temperature returned to normal and blood culture was sterile. Forty-eight hours later, however, there was a recrudescence of fever, and blood culture was again positive. The same regimen was followed for a second five day period and a like result was obtained. Forty-eight hours after therapy was discontinued blood culture revealed 4 colonies per cubic centimeter. Treatment was therefore resumed for a third five day period, and, in an attempt to terminate the infection, the dosage was increased to 20,000 units every three hours intramuscularly for an additional three days. A sterile blood culture was again obtained, and the patient's condition showed a remarkable improvement. Within a few days, however, cultures again became positive, and it appeared probable that the infection could not be terminated with the amount of drug then available. Up to this time a total of 1,600,000 units had been administered. During the succeeding five months six further courses of penicillin were given, but, since there was no assurance at any time that further supplies would become available, treatment was not continued for longer than five days in any one course. On each occasion the temperature promptly returned to normal and continued so for periods varying from one to three weeks. The patient remained in excellent general health, but blood cultures taken during the febrile periods were uniformly positive. It was a matter of great interest that throughout the entire illness the organism remained fully as sensitive to penicillin *in vitro* as it had been originally. Although the infection persisted after a total of 6,700,000 units had been given intermittently over a period of six months, the response was sufficiently striking to warrant the hope that a favorable result might be obtained if a supply of penicillin was available for prolonged, intensive therapy.

Follow-up note: Three months later the patient received intensive penicillin and heparin therapy under the direction of Dr. Leo Loewe of the Jewish Hospital of Brooklyn. He reports that she is now living a normal, active life and is completely well nine months after discontinuance of all treatment.³

CASE 4.—M. L., a woman aged 23 with a history of polyarthritides at the age of 8 followed by rheumatic mitral disease, was admitted on March 30, 1943 with fever, malaise and muscle aches of two weeks' duration. Four blood cultures were positive for *Str. viridans*. The organism could not be classified serologically and was fully as sensitive to penicillin as the standard strain of hemolytic streptococcus. On the eighth hospital day the patient developed a severe pain in the left upper quadrant which was interpreted as a splenic infarct. Penicillin therapy, 10,000 units every three hours intramuscularly, was instituted and continued for eight days. The temperature gradually returned to normal, and blood culture became sterile. On the eighth day she passed an embolus to the left leg in either the lower femoral or popliteal artery. Penicillin dosage was increased to 20,000 units every three hours intramuscularly for two days, and thereafter all therapy was discontinued. Total penicillin administered was 830,000 units. The subsequent course was uneventful. Blood cultures were uniformly sterile, and the erythrocyte sedimentation rate gradually fell from 121 to 35 mm in one hour. On June 3 she was discharged to a convalescent home, the only complaints being occasional sticking sensation in the splenic region and some pain in the left foot after walking. Since June 1943 the patient has been seen on frequent occasions. Innumerable blood cultures have been sterile. She looks the picture of health and lives a normal, active life.

CASE 5.—H. E., a woman aged 23, with aortic and mitral rheumatic heart disease, was first seen on April 14, 1943. Fever had been present for two months, several petechiae were noted, and the spleen was palpable. Numerous blood cultures were positive for *Str. viridans*, approximately 40 colonies per cubic centimeter. The infecting organism could not be classified serologically and was one fourth as sensitive to penicillin as the standard strain of hemolytic streptococcus. Penicillin was started, 10,000 units every three hours intramuscularly, and continued for eight days. The temperature gradually fell, and blood cultures became sterile. Immediately on discontinuance of therapy, however, there was a recrudescence of fever, and blood cultures again became positive. After an interval of three days, penicillin was resumed and continued for a second period of seven days. Blood culture again became sterile, and the temperature remained normal for the following three weeks. During this period, however, blood cultures again became positive and on May 9 penicillin was resumed. On this occasion she was given 20,000 units every three hours intramuscularly for five days. Although the patient continued in excellent clinical condition, a positive culture was again obtained at the end of this time. In the succeeding two months she was given six further short courses of penicillin, and on each occasion an essentially similar result was obtained. At no time, however, did the blood culture remain sterile for longer than a week. Throughout the entire period great difficulty was experienced in obtaining further supplies of penicillin, and it was never possible to arrange for a program of sustained therapy. On July 24 penicillin treatment was discontinued after a total of 7,960,000 units had been administered. On August 13 she was placed on sulfamerazine. The response was not favorable, and during the succeeding three weeks a low grade fever continued. Blood cultures remained positive. On September 4 a terminal episode occurred which was interpreted as a cerebral embolus.

The autopsy findings were of considerable interest, and the salient features of the pathologist's report are here presented:

"The lesions in the heart were much less extensive than is usually the case in subacute bacterial endocarditis. . . . In general, except for evidence of slight activity, the lesions were old and healed. . . . Careful microscopic examination of a large number of sections of tissue from the heart, all of them stained by the Gram-Weigert method, failed to disclose any detectable micro-organisms. . . . In view of the histologic findings in the heart I feel quite certain that the terminal bacteremia was not the result of the spread of micro-organisms from the heart itself, for the lesions were minimal and bacteria apparently absent. . . . In my opinion the probable source

3. This follow-up report is included by permission of Dr. Loewe.

of the terminal bacteremia was in the brain. . . . Unfortunately, however, the brain was not examined at autopsy and therefore one can only speculate about the cerebral lesions."⁴

SUMMARY OF RESULTS IN PRELIMINARY GROUP

The results obtained in the treatment of this preliminary series of 5 cases may be summarized as follows: In 2 cases the outcome was apparently successful; after periods of twenty-two and eighteen months respectively the patients are in excellent health and leading normal, active, lives. In the 3 remaining cases the response was satisfactory as long as penicillin was administered in the manner described, but the infection recurred when therapy was discontinued. Two of these patients were maintained in excellent general condition for many months and ultimately received intensive penicillin therapy combined with heparin, with completely satisfactory results. The third patient succumbed to a cerebral accident six weeks after cessation of penicillin. Postmortem examination of the heart in this case revealed substantial healing of the endocardium with only slight evidence of residual infection.

In view of the encouraging results in this preliminary series, it was hoped that the clinical trials might be continued in selected cases. In the meantime, much valuable experience has been obtained in the administration of penicillin in a variety of other infections,¹ and it was realized that the methods employed in the foregoing group of cases left much to be desired. However, further supplies of the drug could not be obtained for cases of this disease and the study was therefore temporarily abandoned. In January 1944 limited amounts of penicillin again became available for the treatment of cases of bacterial endocarditis and since then it has been possible to treat 23 additional patients. The second part of this report deals with the results obtained in the treatment of the first 15 of these.

PART II: CASES TREATED IN 1944

Just at the time when it became possible to resume the clinical trials, we learned of the work of Loewe and his associates⁵ at the Jewish Hospital in Brooklyn. These workers reported the apparently successful treatment of 7 consecutive cases of subacute bacterial endocarditis by the combined use of penicillin and heparin. In their series penicillin was administered as a continuous intravenous drip and heparin was given subcutaneously in a special menstruum. Apart from any possible role which heparinization of the blood might play in controlling the infection, this type of anticoagulant therapy appeared to offer the following advantages: (a) The method of subcutaneous administration of heparin was apparently safe and practical, (b) the procedure might be of value in the therapy of cases in which major embolic complications developed, and (c) by preventing clotting of the blood in the veins used for continuous infusion the procedure would remove one of the major difficulties accompanying the technic of prolonged intravenous therapy. Accordingly, heparin was employed in all the cases treated between January and September 1944.⁶ In several instances, however, the amount of heparin used is comparatively small. In some cases penicillin was administered by continuous

intravenous drip and in other cases by intramuscular injection at frequent intervals. Recently a continuous intramuscular drip has been employed with apparently satisfactory results.⁷

Synopses of the 15 cases, together with a description of the additional treatment given in 1 of the cases already reported in the preliminary series, follow:

CASE 7.—R. J., a Negro girl aged 17 with a history of rheumatic fever at the age of 6 and known rheumatic heart disease, was admitted on Jan. 5, 1944 with symptoms of malaise, fever, night sweats and joint pains of one month's duration. Examination revealed conjunctival petechiae, an enlarged heart with mitral stenosis, a palpable spleen and temperature of 103 F. Four blood cultures were positive for *Str. viridans* with 78 to 137 colonies per cubic centimeter. The organism was one half as sensitive to penicillin as the standard strain of hemolytic streptococcus. On January 13 penicillin was started, 20,000 units every four hours intramuscularly. On the ninth day the dose was increased to 20,000 units every three hours and therapy was continued for five more days, making a total of 1,900,000 units. The temperature became normal within forty-eight hours after the institution of treatment but rose again to 101 F. shortly thereafter. This rise was accompanied by joint pains, elevation of the erythrocyte sedimentation rate from 25 to 94 mm. in one hour, and electrocardiographic signs of rheumatic activity. On the administration of salicylates the temperature promptly returned to normal and the joint pains disappeared.

Heparin was administered subcutaneously as follows: January 13, 200 mg.; January 17, 300 mg.; January 22, 200 mg., and January 26, 200 mg. On January 18 the coagulation time rose to one hundred and fourteen minutes and remained between twenty and sixty minutes for several days but rose again to one hundred and fifteen minutes on January 27. On this day the patient complained of "mistiness of vision," and examination revealed bilateral preretinal hemorrhages in the macular region. She was given a blood transfusion of 300 cc.; and the coagulation time promptly returned to ten minutes. The hemorrhages resolved rapidly, and after two weeks her vision again became normal.

The subsequent course was uneventful. On February 10 there were signs suggesting a splenic infarct but no rise in temperature or erythrocyte sedimentation rate occurred, and blood cultures in succeeding weeks were sterile. The patient remained in the hospital until March 27, progressively becoming more active. After two months in a convalescent home she returned to work. Since March, blood cultures have remained consistently sterile and the erythrocyte sedimentation rate has been normal. She has gained 30 pounds (13.6 Kg.), lives an active, normal life and enjoys excellent health.

CASE 2.—H. L. (additional report). Following discharge on March 28, 1943 the patient was maintained on sulfadiazine, 4 Gm. a day, and, although blood cultures continued to be positive, her general condition remained good until January 1944. Thereafter the situation deteriorated materially, with an increase in all symptoms as well as the development of a mycotic aneurysm of the right radial artery. On readmission, March 14, 1944, she was acutely ill and blood culture revealed *Str. viridans*, 102 colonies per cubic centimeter. Penicillin was started on March 18 by continuous intravenous drip. Because of technical difficulties with the infusion the patient received only about 100,000 units every day, but the clinical response was very satisfactory. After twelve days intramuscular injections were employed, and she was given 25,000 units every three hours for eleven days, the total amount administered being 3,542,000 units. Heparin was not given because the clotting time was found to be thirty minutes and the prothrombin time 27.7 seconds, possibly as the result of salicylate therapy. On April 6 a surgical consultant advised ligation of the aneurysm of the radial artery to prevent possible rupture. Following diodrast injection for arteriography, it was found that the

4. Dr. L. W. Gorham, physician in chief of the Albany Hospital, cooperated in the management of this case, and Dr. A. W. Wright, pathologist of the Albany Hospital, made the pathologic report available.

5. Loewe, L.; Rosenblatt, P.; Greene, H. J., and Russell, M. Combined Penicillin and Heparin Therapy of Subacute Bacterial Endocarditis. *J. A. M. A.* 124:144 (Jan. 15) 1944.

6. Dr. Loewe and his associates provided the heparin used in the present study and cooperated in the management of this type of anticoagulant therapy.

7. Harris, F. L.: Continuous Intramuscular Infusion of Penicillin. *J. A. M. A.* 126:232 (Sept. 23) 1944.

brachial artery had become thrombosed proximal to its bifurcation, and the aneurysm ceased to pulsate. She was given 100 mg. of heparin subcutaneously to prevent further thrombosis in the collaterals. Circulation was gradually reestablished in the brachial artery, and all trace of the aneurysm ultimately disappeared. Following cessation of penicillin on April 10 her course continued to be afebrile; blood cultures remained sterile, and she was discharged on May 2. Since then she has been seen on frequent occasions. She has regained her original weight, is doing her own housework and states that she feels as though she never had been ill. Frequent blood cultures have been sterile.

CASE 12.—N. W., a boy aged 13 years with a history of rheumatic fever at the age of 4 and known rheumatic heart disease since 1935, developed fever and malaise in December 1943. Blood culture in January 1944 at another hospital yielded *Str. viridans*, and on February 2 sulfadiazine was started, 1 Gm. every three hours. On the following day there was a complete hemiplegia. On February 15 he had severe pain in the right flank, which was interpreted as a renal embolus. On March 6 he was admitted to the Babies Hospital. The boy was pale, feverish and wasted, chronically and severely ill, with weakness of the right facial muscles and spastic paralysis of the right side of the body. The skin over the coccyx was red and atrophic. The heart showed aortic and mitral disease. Five blood cultures were positive for *Str. viridans*, which was as sensitive to penicillin as the standard strain. Sulfadiazine, 4 Gm. a day, was given from March 9 to April 10 without significant effect. Although the prognosis was considered hopeless, penicillin was started on April 13, 120,000 units every day by intravenous drip. A single injection of 100 mg. of heparin was given subcutaneously on April 13 and the clotting time remained above thirty-five minutes for eight days. During the first five days of penicillin therapy the response appeared to be favorable. His temperature fell to levels around 100 F. but rose to 104 F. on April 18 and remained between 103 and 105 F. for the next week. On April 20 he vomited some clotted blood, and thereafter heparin was discontinued. On three occasions severe thrombophlebitis developed at the sites of the intravenous needle, but the muscles were so wasted and atrophic that intramuscular injections seemed impossible. Because of failure to improve and the generally hopeless outlook (hemiplegia and extensive decubitus), therapy was stopped on the twelfth day after a total of 1,410,000 units had been administered. Six days after cessation of therapy the temperature became normal and remained so. Blood cultures were sterile, the decubitus gradually healed and there was some improvement in the hemiplegia. He remained in the hospital until September 16, gradually gaining weight and strength. From July 25 to August 2 he was treated with sulfadiazine for acute tonsillitis and made an uneventful recovery. One blood culture on August 21 showed a few colonies of streptococci in one flask, but five subsequent cultures were negative. When last seen in October he had gained 22 pounds (10 Kg.) and there was no clinical evidence of infection. The function of the right arm and leg showed continued improvement, and blood cultures were sterile.

CASE 14.—C. A., a man aged 31, was admitted on April 19, 1944 with a three months history of fever, malaise, weight loss, generalized aches and pains and tender finger tips. The past history was exceedingly complicated and included chorea at the age of 8 and the development of a parkinsonian syndrome following encephalitis at the age of 13. Three and a half years previously he had been admitted to the Presbyterian Hospital and at that time was found to have classic subacute bacterial endocarditis. *Str. viridans* was obtained in seven blood cultures. From Oct. 22, 1940 to Dec. 20, 1940 he was given 6 Gm. of sulfapyridine daily. The clinical response was very satisfactory; the temperature gradually returned to normal, and blood cultures became sterile. Following discharge on December 20 he was maintained on sulfapyridine, 6 Gm. a day, until March 4, 1941. Chemotherapy was then discontinued, and in the succeeding three years there was no evidence of a return of the infection.

As a matter of historical interest it may be noted that on Oct. 16 and 17, 1940, preceding sulfonamide therapy, this patient was given injections of a penicillin solution prepared in our own laboratories by Dr. Karl Meyer. Although proved to be highly effective in the treatment of experimental infections in animals, the potency of this preparation was not titrated in Oxford units. Further penicillin therapy was not possible at that time because of the limited amount of material available. Although the quantity was too small to achieve a significant result, it is believed that this is the first occasion on which penicillin was employed clinically in this country.

On readmission, April 19, 1944, the patient was found to have a temperature of 103 F., an enlarged heart, aortic diastolic murmur, palpable spleen and clubbed fingers. Four blood cultures were positive for *Str. viridans*, 23 colonies per cubic centimeter, and the organism was one half as sensitive to penicillin as the standard strain. On April 25 penicillin was started, 200,000 units every day by intravenous drip. The clotting time was maintained between twenty-four and ninety minutes by subcutaneous injections of 200 mg. of heparin on April 20 and May 4. The temperature promptly returned to normal. On the fifth day penicillin dosage was changed to 25,000 units every three hours intramuscularly because of difficulty with veins. On the eighth day he developed a left hemiplegia and aphasia, apparently as the result of an embolus in the right internal capsule. The temperature rose to 104 F., gradually returning to levels of 99 and 100 F. at the end of the second week. After 3,090,000 units of penicillin had been given over a sixteen day period, therapy was stopped to permit evaluation of the situation. Blood cultures remained sterile and the clinical course was afebrile. The patient was observed in the hospital for three months, during which time there was some improvement in the hemiplegia and aphasia. On August 15 he was transferred to another institution for chronic care. Since then there has been no evidence of a recurrence of the infection and the general health of the patient has continued to improve.

In this unusual case it seems reasonable to suppose that the second illness, which occurred three and a half years after the first, represented a new infection rather than a recurrence of the original one.

CASE 15.—A. V., a man aged 37, without recognized history of rheumatic fever, was admitted on April 17, 1944 with a three months history of fever and weight loss. Physical examination revealed mitral and aortic murmurs and a palpable spleen. Four blood cultures were positive for *Str. viridans*, approximately 12 colonies per cubic centimeter. The infecting strain was one half as sensitive to penicillin as the standard strain of hemolytic streptococcus. Penicillin was started on April 26, 200,000 units daily by intravenous drip. The coagulation time was maintained between twenty and sixty minutes by the administration of 200 mg. of heparin subcutaneously on four occasions. The clinical course was uneventful. The temperature showed some elevation in the latter part of therapy, apparently as a result of reaction to heparin. Penicillin was discontinued on the twenty-first day, after a total of 4,150,000 units had been administered. After cessation of therapy the patient continued to have a low grade fever for twelve days. Blood cultures, however, remained sterile and he was discharged June 8, afebrile and in good clinical condition. Since then he has been seen on frequent occasions and has remained asymptomatic. The erythrocyte sedimentation rate remained elevated for several months but gradually returned to normal. He has gained 30 pounds (13.6 Kg.) in weight, looks the picture of health and has resumed his former occupation.

CASE 16.—O. M., a man aged 30 with a history of rheumatic fever at the age of 8, developed malaise, fever, cough and painful-finger tips in February 1944. On admission, April 26, there were petechiae on the soft palate, aortic and mitral disease, palpable spleen and clubbing of the fingers. Three blood cultures

were positive for *Str. viridans*, approximately 20 colonies per cubic centimeter. The organism was one eighth as sensitive to penicillin as the standard strain. Penicillin, 200,000 units every day by intravenous drip, was started on May 4, and clotting times were maintained between twenty and seventy minutes by subcutaneous heparin, 200 mg. every four or five days. The patient continued to have a low grade fever for two weeks, and then his temperature rose to 103 F., presumably as the result of thrombophlebitis at the site of the intravenous drip. At the end of the third week of therapy the temperature became normal and penicillin was stopped, after a total of 4,150,000 units had been given. Twenty-four hours later his temperature rose again, and blood culture two days later was positive. On May 29 therapy was resumed. Because of difficulty with veins he was given 25,000 units every three hours intramuscularly, and treatment was continued for two weeks. Fever persisted, and blood cultures remained positive. Accordingly, the dosage was increased to 300,000 units every day by intravenous drip, and therapy was continued for two more weeks. On this regimen the blood culture again became negative, although low grade fever continued. Therapy was discontinued on June 26, after a total of 7,100,000 units had been given. Four days later, however, blood culture was again positive. On July 5 penicillin was resumed, and on this occasion the patient was given 300,000 units daily by intravenous drip and 6 Gm. of sulfadiazine orally. Because of several episodes of phlebitis, it became necessary to resort to intramuscular injections after five days, and sulfadiazine was increased to 9 Gm. daily. This regimen was continued until July 17. In the succeeding two weeks his clinical condition improved, the spleen no longer was palpable and blood cultures were sterile. Although there was much doubt that the infection had been terminated, the patient was discharged on August 4 on a maintenance dose of 6 Gm. of sulfadiazine daily. One week later blood culture was again positive and he was readmitted on August 21.

Up to this time he had received a total of 15,700,000 units of penicillin in three courses over three months. Since his general condition remained excellent, and since the infecting strain was just as sensitive to penicillin as it had been originally, arrangements were made for resumption of intensive therapy. Starting on August 22 he was given 50,000 units approximately every two and a half hours by intramuscular injection for eighteen days, followed by 500,000 units daily by intravenous drip for a further period of twenty-three days. While on intravenous therapy the clotting time was maintained between thirty-six and seventy-four minutes by the administration of 200 mg. of heparin subcutaneously on three occasions. In spite of this intensive therapy he continued to have an irregular fever, and blood cultures were intermittently positive. Penicillin treatment was discontinued on October 3, and maintenance doses of sulfadiazine were instituted. Thereafter blood cultures continued to be positive. Although the patient's general condition had deteriorated very little since his first admission five months previously, the administration of 36,700,000 units of penicillin failed to terminate the infection. At present he is being maintained on sulfonamides pending a decision regarding further penicillin therapy.

CASE 19.—G. L., a woman aged 21 with a history of rheumatic fever at the ages of 13 and 16 and known to have mitral and aortic disease, was delivered of a normal child on March 5, 1944. The postpartum course was uneventful. On July 7 she complained of fever, chills and general malaise and was admitted five days later. On admission the temperature was 103 F. and the spleen was palpable. Five blood cultures were positive for *Str. viridans*, and the strain was one eighth as sensitive to penicillin as the standard strain. Penicillin was started on July 22, 40,000 units every three hours intramuscularly. The intramuscular route was chosen because of poor veins, and larger doses than usual were given because the infecting strain was relatively resistant. The clotting time was maintained between twenty-five and sixty minutes by subcutaneous heparin, 200 mg. on two occasions and 100 mg. on one occasion. The course was uneventful and essentially

afebrile. Blood culture was sterile three days after the institution of therapy and remained so thereafter. Penicillin was stopped after 3,880,000 units had been given over a twelve day period. She was allowed home sixteen days later in order that she might be with her husband during his leave from the Army. During the next three months she gained weight and strength and now feels and looks the picture of health. Blood cultures have remained sterile.

CASE 20.—E. C., a woman aged 40 with known rheumatic fever in childhood, was admitted on June 27, 1944 with a history of fever and malaise of two months' duration following dental extractions. Examination showed the presence of a mitral lesion, and five blood cultures were positive for *Str. viridans*. The infecting strain was one half as sensitive to penicillin as the standard strain. On August 8 penicillin was started, 25,000 units every three hours intramuscularly. The intramuscular route was used because of lack of suitable veins. Clotting time was maintained between twenty-six and seventy-seven minutes by the administration of 200 mg. of heparin every four or five days. On August 26 the clotting time rose to one hundred and ten minutes and the patient developed epistaxis. A transfusion was given with immediate satisfactory response. She continued to have a low grade fever, but the course otherwise was uneventful. Therapy was continued for three weeks, at which time a total of 4,200,000 units of penicillin and 1,000 mg. of heparin had been administered. Although her clinical condition was highly satisfactory, blood culture taken ten days after cessation of penicillin was positive. On succeeding days the temperature rose slightly, and penicillin therapy was reinstituted on September 17. On this occasion the dose was increased to 40,000 units every three hours intramuscularly, and treatment was continued for twenty-one days. Heparin, 200 mg., was administered subcutaneously on three occasions. The temperature remained below 100 F. and the patient was essentially asymptomatic. During the second course 6,360,000 units of penicillin was administered. Since discontinuance of therapy on October 7, blood cultures have remained sterile, the erythrocyte sedimentation rate has continued to fall and the patient states that she feels perfectly well.

The results of treatment in these 16 cases may be summarized as follows: In 11 patients the infection has apparently been terminated. All 11 have remained bacteria free and in excellent general health for periods of three months or longer since therapy was discontinued. One additional case has apparently responded satisfactorily but sufficient time has not yet elapsed to permit proper evaluation of the situation. In 2 patients the infection was temporarily controlled but recurred when treatment was stopped. Two patients succumbed; in each instance the terminal episode was apparently a cerebral embolus.

ANALYSIS OF CASES

In order that the experience gained in the treatment of the 20 cases described in this report may be helpful as a guide in the future therapy of this disease, the material is analyzed from several points of view.

Selection of Cases.—As stated in the introduction, the 5 cases described in the first part of this report were selected on a basis of the good clinical condition of the patient and a well defined sensitivity to penicillin on the part of the infecting strain. With the exception of 3 patients who were not accepted for treatment because the infecting organism was found to be almost totally resistant to penicillin, the 15 cases described in the second part of the report were unselected and represented consecutive hospital admissions from January to August 1944. Some of the patients were desperately ill when therapy was started, while others were in good general condition. It is worth commenting that the

patient in the poorest condition clinically (patient 12) made an apparently uneventful recovery, while 1 of the patients in excellent general condition (patient 16) failed to respond.

Primary Cardiac Disease.—In 18 of the cases the underlying cardiac disease was rheumatic in nature and in the remaining 2 congenital. Of the cases of congenital heart disease, 1 responded in a most satisfactory manner and the other was resistant, although the infecting strain was highly sensitive to penicillin. In the group with rheumatic heart involvement there were 10 cases of mitral disease and 8 cases of combined mitral and aortic disease. No correlation was observed between the valvular distribution of the rheumatic lesion and the outcome of therapy.

Probable Duration of Infection.—It was obviously impossible in many instances to determine even approximately the time of onset of the infection; in other cases the date could be fixed with a reasonable degree of certainty. As shown in the table, the probable duration of the infection at the time therapy was started varied from two weeks to fifteen months. In the majority of the cases symptoms had been present from two to three months. No direct relationship appeared to exist between the duration of the disease and the outcome of therapy. Two of the cases of shortest duration, two weeks and one month respectively, showed a very prompt response, but another case known to have been infected for fifteen months also responded favorably. On the other hand, 2 cases of two and two and a half months' duration respectively proved to be exceedingly refractory.

Penicillin Sensitivity of the Infecting Strain.—The method used in the determination of penicillin sensitivity is described elsewhere.² For convenience, the sensitivity of each strain was compared with that of a standard strain of group A hemolytic streptococcus (strain C203Mv). One strain was found to be twice as sensitive as the standard strain, five strains were equally sensitive, seven strains were one half as sensitive, three strains were one fourth as sensitive and four strains were one eighth as sensitive. In terms of the amount of penicillin, the sensitivity of the standard strain is such that the growth of a 10^{-2} dilution, containing approximately 3 million organisms, is inhibited by 0.017 unit. The approximate amount of penicillin necessary to inhibit growth of the arbitrary standard seeding of one strain was 0.008 unit, of five strains 0.017 unit, of seven strains 0.035 unit, of three strains 0.07 unit and of four strains 0.14 unit.

Analysis of the results of treatment according to the nature of the infecting strain offers little information of value at the present time. One case in which the organism was only one eighth as sensitive as the standard strain proved refractory (case 16), but in 3 other cases in which the organism was equally resistant the response was satisfactory (cases 9, 13 and 19). Two cases in which the organism was very sensitive (cases 6 and 17) failed to respond, while 3 other cases in which the strain showed the same degree of sensitivity responded promptly (cases 4, 10 and 12). It should be noted, however, that the results in those cases in which the strains belonged serologically to groups F and H were uniformly good. Mention has been made elsewhere of the fact that 3 other cases were not accepted for treatment because the infecting strains were highly resistant as judged by *in vitro* tests. The organisms

from these cases were from one hundred and sixty to eight hundred times as resistant as the standard strain. At the present time data are being accumulated on the relationship between the *in vitro* sensitivity of strains and the penicillin blood levels necessary to effect sterilization of the blood stream. It is believed that these studies will provide information of value in the future therapy of cases of this disease.

ANALYSIS OF THERAPY

In the present series of cases the method of penicillin administration, dosage and length of treatment varied greatly. As previously mentioned, the amount of drug available while the preliminary group of 5 cases was being treated was very limited, and it was not possible to plan for a sustained therapeutic regimen. As the supply increased, the methods of administration and dosage became more uniform, but it is felt that much further experience will be necessary before a standardized procedure is established.

Methods of Penicillin Administration.—In 7 cases the drug was administered by intramuscular injection at frequent intervals, usually every three hours. In 5 cases an intravenous drip was employed, and in 8 cases both methods were used at different times, as circumstances dictated. The results were apparently completely satisfactory in 5 of the 7 cases treated by the intramuscular route and in 4 of the 5 cases treated by intravenous drip. The two groups are so small, however, and other factors so variable that no conclusions can be drawn from these results. Each method possesses distinct advantages as well as disadvantages. The method of frequent intramuscular injections is simple and less trying on the patient but suffers from the disadvantage of failing to produce uniformly effective blood levels of penicillin. The technic of the continuous intravenous drip is more difficult and thrombophlebitis frequently develops at the site of injection, but uniformly effective blood levels are maintained throughout. More recently a continuous intramuscular drip, as suggested by the English workers and described in this country by Harris,⁷ has been used with apparently satisfactory results. It seems possible that this will represent the method of choice in the future.

Dosage of Penicillin.—The daily dosage varied from as little as 80,000 units in 1 of the early cases to as much as 500,000 units in 1 of the more resistant cases. The total amount given to each patient ranged from 830,000 to 36,700,000 units. It became apparent very early in the clinical trials that the requirements of each case varied greatly, and therapy was largely determined empirically. As experience accumulated a regimen of 200,000 units daily for three weeks was established as a standard. This appeared to be adequate for the majority of cases, but in 3 instances signs of infection recurred when treatment was discontinued and additional therapy was given. In succeeding courses the daily dose was increased to 300,000 or 320,000 units and in 1 case to 500,000 units, and treatment was continued for a longer period of time. Two of the cases failed to respond to this increased dosage, but in 1 case the result was apparently satisfactory.

Duration of Therapy.—In the present series, therapy was continued for periods varying from ten to sixty-two days. Cases 4, 7, 8, 12 and 19 were treated for ten, fourteen, fourteen, twelve and twelve days respectively, and the results were uniformly satisfactory. On the

* Treated by Dr. Leo Loew, Jewish Hospital of Brooklyn, to whom the patient was referred for combined penicillin and heparin therapy.

other hand, in cases 16 and 17 the infection persisted after one hundred and three and eighty-five days of treatment respectively. It is apparent, therefore, that the time for which treatment should be continued varies greatly from case to case. As the study proceeded, and as a more uniform supply of drug became available, the majority of cases were treated for an initial period of twenty-one days. If the infection persisted at the end of this time, further courses of variable length were given as circumstances indicated. The effect of larger daily doses of penicillin administered for shorter periods of time will be the subject of further investigation.

Heparin.—In the preliminary group of 5 cases treated in 1942 and 1943, heparin was not employed. At the time when arrangements were made to resume the study, Loewe and his associates⁸ reported their results with combined penicillin and heparin therapy. Since major embolic phenomena proved to be a serious complication in the preliminary group and since the method of administering heparin subcutaneously, as described by Loewe, appeared to be a safe procedure, this type of anticoagulant therapy was employed in the cases subsequently treated. In 1 patient the anticoagulant was used only to prevent thrombosis in collateral vessels following ligation of a mycotic aneurysm of the ulnar artery. In the majority of patients the coagulation time was maintained between thirty and sixty minutes; in other cases less intensive therapy was employed. The amount of heparin necessary to induce this change in clotting time varied greatly from patient to patient. Some patients received 200 mg. every four or five days and others lesser amounts. The majority of the patients tolerated the treatment reasonably well, but others complained of pain at the site of the injections. Not infrequently the administration of heparin led to systemic reactions with sharp febrile responses, which confused the clinical picture considerably.

Hemorrhagic complications resulting from heparinization were definitely observed in only 1 instance. In case 7 preretinal hemorrhages occurred in both macular regions when the clotting time was observed to be in the neighborhood of one hundred and fifteen minutes, which is much above the recommended safe clotting time of thirty to sixty minutes.⁸ A transfusion was given as soon as the complication was recognized, and the hemorrhages resolved without residual impairment of vision. In 2 other cases bleeding episodes occurred but heparin could not be incriminated with certainty. Major embolic episodes were observed in 4 patients who received adequate heparinization, but in 2 of these the event occurred several days after treatment had been discontinued. One patient developed a cerebral embolus at a time when his blood was adequately heparinized.

Present experience is inadequate to form an opinion as to the value of heparin therapy as an adjuvant to penicillin in the treatment of this disease. It will be noted, however, that the response in 2 cases in the preliminary series was satisfactory without heparin, and more recently several additional cases have responded satisfactorily without anticoagulant therapy. Much further experience in a considerable series of cases treated with and without heparin will therefore be necessary before an opinion can be expressed as to its value.

RESULTS

It is recognized that a long follow-up period will be necessary before the ultimate outcome can be determined in a chronic disease such as subacute bacterial endocarditis, in which the infection may remain latent for considerable periods of time. Present experience with penicillin therapy, however, suggests that the prognosis is excellent in cases which remain clinically and bacteriologically free from infection for a period of four weeks after treatment has been discontinued. At the present time 14 of the 20 patients are in excellent general health and have been free from all evidence of infection for at least three months since treatment was stopped. One additional patient is in excellent health and has been free from all evidence of infection for four weeks. It is believed that the prognosis in this case is good. In 12 of the 14 patients the follow-up period has been five months or longer, and 2 patients have been followed for periods of eighteen and twenty-two months respectively. Two patients responded temporarily to the administration of penicillin, but in spite of protracted treatment with large doses a relapse occurred when therapy was discontinued. These 2 patients are still in excellent general condition, and it is hoped that it will yet be possible to arrange for a therapeutic regimen which will finally terminate the infection. The remaining 3 patients have succumbed. In each instance death was apparently due to a cerebral embolus. In 2 of the fatal cases the infection was still present at the time of death, and in the third the situation was in doubt.

The change which has taken place in the 15 patients who have apparently recovered has been truly remarkable. With the exception of 3 patients, 2 of whom suffer from hemiplegia and 1 who subsequently developed a coronary occlusion, all the "recovered" patients have returned to work or resumed their former occupations.

SUMMARY

Twenty patients with subacute bacterial endocarditis were treated with penicillin. A preliminary group of 5 were treated in 1942 and 1943, and 15 were treated in 1944. The infecting organism was a streptococcus in all instances. Heparin was employed as an adjuvant to penicillin in the treatment of the majority. While it is recognized that a long follow-up will be necessary before the ultimate outcome is established, therapy was apparently successful in 15 of the 20. All 15 patients are now clinically and bacteriologically free from infection. In 2 of the remaining 5 patients the infection was controlled as long as penicillin was administered, but a relapse occurred when therapy was discontinued. These 2 patients are still in excellent general health, and it is hoped that it will yet be possible to arrange for a therapeutic regimen which will produce a satisfactory outcome. The remaining 3 patients succumbed. In each instance death was apparently due to a cerebral embolus. In 2 of the fatal cases the infection was still present at the time of death, and in the third the situation was in doubt. Further experience is necessary before an opinion can be expressed regarding the value of heparin as an adjuvant to penicillin in the treatment of this disease.

CONCLUSION

Patients with subacute bacterial endocarditis should be treated with penicillin if the infecting organism is a streptococcus sensitive to the action of the drug.

8. Loewe, Leo, and Rosenblatt, Philip: A New Practical Method for Subcutaneous Administration of Heparin, *Am. J. M. Sc.* 208: 54 (July) 1944.

ADDENDUM

Since the preparation of this report, 7 additional patients with subacute bacterial endocarditis have been treated with penicillin. In the last 5 of these penicillin was administered by continuous intramuscular drip and heparin was not employed. The results indicate that the response was as favorable in this group as in those patients in whom heparin was used. In 6 patients the infection has apparently been terminated. The seventh patient relapsed after one course and is now receiving additional therapy.

Comparative studies, which will be reported in detail elsewhere, show that as a rule higher blood levels are obtained in patients receiving penicillin by continuous intramuscular drip than in those receiving continuous intravenous drip. Since the intramuscular drip is also better tolerated by the patient and the technic is simpler, this method of administration appears to be the one of choice for patients receiving penicillin for prolonged periods.

THE TREATMENT OF SPONDYLOLISTHESIS

WALTER E. DANDY, M.D.
BALTIMORE

This study was begun with the thought that fixation of opposing vertebrae resulting from complete removal of an affected disk at the site of the spondylolisthesis would produce a much simpler and more effective fusion of the spine than the customary fusion with bone grafts. The observations from the series of patients operated on has led to unexpected conclusions; i. e. (1) that the spondylolisthesis is usually responsible for only part and at times none of the symptoms, (2) that in most (not all) instances it is not the spondylolisthesis or even the disk at its site that causes the symptoms but rather another disk or disks and (3) that therefore cure usually depends more on removal of the other disk or disks than on the one at the site of the spondylolisthesis, though this too must be extirpated.

The principal reasons for these seemingly paradoxical conclusions are that: 1. In only 3 of the 20 cases was there a protruding disk at the site of the dislocated vertebra. 2. In each of 3 cases there was a single and in 2 other cases two large protruding disks at other interspaces, whereas there was no protrusion at the site of the dislocation. 3. In only 2 of the 20 patients was no defective disk found in addition to the one at the spondylolisthesis (and as these 2 patients are not cured it is probable that they too have another disk). 4. Moreover, these statistical studies are strikingly similar to those for defective disks without spondylolisthesis. In a recent publication it was stated that about 80 per cent of defective disks were multiple; in this series of cases 90 per cent were multiple and it is quite probable that all are multiple, as the remaining 2 cases are not cured. It is difficult to believe that other disks are not always affected when the spinal column is thrown out of line by the spondylolisthesis. 5. It was also stated that only about 25 per cent of all disks were protruding, the remainder being of the small or so-called concealed type. From this group of cases 44 disks were removed and of these 11, or 25 per cent, were protruding. From these figures therefore there is no difference between the findings with and without spondylolisthesis.

It is my impression from this analysis that the spondylolisthesis is but an incident in the field of ruptured disks and that, on the whole, while it causes its share of symptoms it causes less than the contiguous disk or disks. Certainly any treatment that neglected the other disks would accomplish little if any result. Moreover, the reason for the development of spondylolisthesis is precisely the same as for defective disks; i. e., the outward shift in the lateral articulations in the lower three lumbar vertebrae and nearly always most pronounced at the fifth lumbar. Here the joint is frequently turned outward 90 degrees from the direction of those at the first and second lumbar vertebrae and in addition the joint is at times flat and vertical and with little or no flanges to keep the joint surfaces from slipping. At the third and fourth lumbar vertebrae these changes are less severe but are still great enough to induce defective disks; occasionally spondylolisthesis can occur at these disks (one in this series). And finally the signs and symptoms of spondylolisthesis are precisely the same as those of defective disks without spondylolisthesis. Only the x-ray appearance makes the differential diagnosis.

FUSION OPERATIONS BY AUTOGENOUS GRAFTS

Heretofore the standard treatment for spondylolisthesis has been spinal fusions with autogenous grafts. This might appear to be at least a rational procedure if the foregoing conclusion that other disks are equally concerned in symptoms was not known. But with this knowledge, fusion without removing the disks accomplishes nothing—it merely covers up the defective disks, both concealed and protruding—and the symptoms continue practically unchanged. From experience with probably 25 cases in which fusion has been done elsewhere I know this to be a fact—the backache and sciatica have continued. From this series 3, or 15 per cent, had had a total of seven fusion operations (done elsewhere) without benefit.

The avoidance of a fusion operation means a great saving to the patient. In the first place it is a prolonged major operative procedure. It is necessary to be hospitalized in a cast for two or three months. Moreover, many grafts are unsuccessful, many absorb; and, if infection should develop, which is a not uncommon experience, much or all of the graft is lost. And when a subsequent operation for removal of the disks is necessary, it makes the procedure exceedingly difficult and at times unsatisfactory. Finally, the graft is contraindicated and useless because it merely covers up the offending disks and adds nothing to the fusion that follows complete removal of the disks.

Following a disk operation there is no need for a cast. The patient can leave the hospital in a week to ten days. A light corset is advised for two or three months.

THE TREATMENT BY REMOVING THE DISKS

The three most important items in treatment are:

1. The complete removal of the affected disks.
2. The recognition of multiple disks.
3. The recognition of small (concealed) disks.

If a disk is thoroughly and painstakingly removed with a curet, it cannot recur. This does not mean that every particle of cartilage must be extirpated, but it does mean that no large amount can remain. The most difficult area of the disk to remove is dorsally on the contralateral side, and a recurrence with sciatica on the opposite side will occasionally occur. The incidence

of this, however, should be low—five times in the last 800 disks. If curets are not very sharp, cartilage may remain in any part of the disk and a recurrence follow. Up to the present writing this has occurred only once. These are only the exceptions that prove the rule and are due to the personal equation, not to the method. When disks recur the cavity in the disk remains open and does not fill with granulations. Under these circumstances the vertebra remains very loose (*mobility test of pressure on the spinous processes*). When a disk has been completely removed, the vertebra becomes absolutely tight and in three months no movement is possible with the maximum pressure on the spinous process, and it remains so. This means that fusion of the vertebrae has been attained. Stabilization of the spine is absolutely necessary for a cure. When the broad surfaces of the vertebrae unite, the fusion is just as perfect as by the most successful spinal graft. Admittedly this is fibrous union at least for a time, but it is nevertheless effective. There is as yet only slight proof that the union eventually becomes osseous, but this should be expected since bony surfaces are denuded of cartilage and it would be difficult to believe that such a course was not inevitable. There has been no evidence from an experience of two and one-half years that a disk once well healed will break down again. As a matter of fact this form of treatment probably induces exactly the same result that obtains when nature, slowly over the course of many years, absorbs the affected disk, a solid fusion resulting, or when nature heals a fractured vertebra including the disk. In a single case, three years after partial removal of a disk, roentgenographic proof of an osseous union has been disclosed. After total removal of a disk the process of healing should be the same.

Without the recognition of small nonprotruding (concealed) disks, the treatment would be entirely ineffectual. They are just as easy to recognize as the larger protruding disks and cause precisely the same though, on the whole, less intense symptoms. Their existence is always demonstrable by the mobility test. In this series the concealed disks numbered 33 (75 per cent) as against 11 (25 per cent) that were protruding. This is essentially the same ratio that obtains in disks without spondylolisthesis.

LOCALIZATION OF THE AFFECTED DISKS

The localization of the defective disks is now readily determined by the mobility of the joint when horizontal pressure is made on the spinous processes. When there is increased movement at the joint a defective disk with defective lateral joints is the cause. It is this movement that produces intensification of the backache on coughing and sneezing. This test may or may not lose its value when disks are narrowed in the x-ray films. But such x-ray findings are pathognomonic of a disk, so that this exception to the test is of no importance. However, in spondylolisthesis the mobility test at the spondylolisthetic disk is in many instances useless because the lateral joints may no longer be in apposition; the entire lamina then becomes so loose that it can be freely moved with the finger (8 cases). One can test the actual mobility of the vertebral bodies by direct pressure on them. In 5 cases with very narrow fifth interspaces it could be determined by pressure on the vertebra that there was no movement of the spine at the site of the spondylolisthesis. This means that the backache was due not to the slipped vertebra but from the contiguous disks or lateral joints. Although the

mobility test is useless at the site of the spondylolisthesis, it is effective in testing for other disks at the fourth and fifth lumbar vertebrae.

ANALYSIS OF CASES

Thirteen patients were males and 7 females. The ages were from 19 to 54. In the youngest patient symptoms began at 15. Three were under 30, 6 in the thirties, 6 in the forties and 5 in the fifties.

Sixteen of the 20 patients complained of pain on coughing and sneezing; in 2 it was absent and in 2 not noted.

Pain in the lower part of the back was present in all cases.

Pain down both legs was noted in 10, down one leg in 9, and in a single case there was no pain in the leg but only in the hip.

The duration of pain before operation was under one year in 3 cases, from one to five years in 5, from five to ten years in 4 and over ten years in 8. Pain was periodic in 17 and constant in 3.

A definite precipitating cause, usually a fall, heavy lift or severe cough, was elicited in 8; no cause was recognized in 12.

The location of the spondylolisthesis was between the fifth lumbar and the sacrum in 19 cases and between the third and fourth lumbar vertebrae in 1. The grade of spondylolisthesis varied from 0.5 to 1.5 cm. A posterior dislocation of the sacrum existed in 12 and an anterior dislocation in 7 cases. The x-ray examination showed great narrowing at the dislocated joint in all cases except 3; in these the joint was narrowed posteriorly only.

The ankle jerk was diminished or absent in 7 cases and unchanged in 13.

Time since operation was fifteen months the longest, from nine to twelve months in 2 cases, from six to nine months in 5 cases, from three to six months in 5 cases and under three months in 7 cases.

The number of disks was one disk for 2 patients (perhaps none, as these are not cured), two disks for 12 and three disks for 6.

Earlier statistics on defective disks placed 98 per cent of all disks at the fourth and fifth lumbar vertebrae. In this series the third disk was defective in 30 per cent of the cases. This is in keeping with, though somewhat higher than, the incidence of disks at the third lumbar in a large series without spondylolisthesis. There can be no doubt of the much higher percentage of disks at the third lumbar than the earlier figures indicated.

One of the patients in this series had the fourth and fifth disks removed a year ago and has just returned for the removal of the third lumbar (protruding) disk. The fourth and fifth laminae were solid (very loose at the first operation). A recurrence was therefore not possible and the offending disk had to be at the third. Pain in the front of the thigh is always indicative of a defective disk at the third lumbar, but this localizing pain may be absent; i. e., there may still be a defective disk at the third lumbar without pain in the front of the leg.

RESULTS

Since these patients have gone only from two weeks to fifteen months since the operation, the permanence of the results is not claimed; but on the basis of similar treatment of defective disks without spondylolisthesis and extending over a longer period of time I see no reason to expect recurrence later. It is believed that the cures will be permanent. For some time after this

study was begun the very high frequency of multiple disks was not appreciated; for that reason 3 of the patients in this series have returned for removal of an additional disk. The time since operation in these 3 cases has been counted from the last operation.

Two patients in the series have had fusion operations done at the time of the disk extirpations by our orthopedic surgeons, who were none too convinced that removal of the disks would induce fusion of the vertebrae. These cases are not considered in estimating the results. All the patients have been followed. Of the remaining 18 patients (excluding the fusions) 11 have gone more than three months since the operation. Of these 6 are symptom free and 2 are nearly so, having only a little pain for a few minutes in the morning after getting out of bed. Of the remaining 3 patients 2, the only ones with single disk removals, almost surely have another disk. However, 1 of these is greatly improved: the sciatica is gone. She complains of pains in the ribs and neck more than the original backache and sciatica, and in view of her psychogenic background I am reluctant to operate again. The other of these 2 has progressive muscular atrophy in addition to his spondylolisthesis. Heretofore I have refused to operate on perhaps half a dozen patients with known disks (but without spondylolisthesis) when progressive muscular atrophy was also present, but 1 was a relatively big, strong man and I thought he could be benefited for several years. He is not improved, and since his atrophy is increasing I do not feel that he should be operated on again. The remaining patient (operated on eight months ago) is not improved. He is waiting to see if he cannot avoid another operation.

Of the 7 patients who have gone less than three months since the operation, 2 have been operated on before (by myself) and have returned only recently for the removal of another disk in 1 case and 3 disks in another. In the latter case we were unable to find entry into the narrow disk at the spondylolisthesis and the fourth disk appeared normal, so that nothing was really done. Backache and sciatica were excruciating and of course unrelieved. For a time the problem of the patient's relief appeared insuperable. Three weeks later both of the sensory roots of the fifth lumbar nerves were sectioned, without relief. It was thought that perhaps the nerves might be compressed by the extreme dislocation of the sacrum. For weeks thereafter he sat up all night, being unable to lie down without more intense pain. Finally two weeks ago his sciatica became more intense on the opposite side. At operation on this side it was possible to enter and curet the cartilage from the disk at the spondylolisthesis, and concealed disks were removed from both the fourth and the third. He was immediately much improved and at this writing (two weeks after operation) the improvement continues. He has been unable to sleep lying down since the operation.

The remaining 3 patients (who have gone six to ten weeks) have been entirely relieved of sciatica, and the backaches are steadily lessening. One has been complicated by a return of an infection that followed a fusion operation a year earlier.

CONCLUSIONS

1. Subjectively and objectively, spondylolisthesis is precisely like defective intervertebral disks. Only the x-ray differentiated the two conditions.

2. For reasons noted in the text, it is my opinion that spondylolisthesis and defective intervertebral disks

are really identical in origin and the treatment is the same; i. e., complete removal of the disks.

3. In at least 90 per cent and probably all of the cases there are two or three disks (including the one at the site of the spondylolisthesis) causing the backache and sciatica, and a cure depends on the recognition and treatment of all the affected disks. The disk at the site of the spondylolisthesis causes no more and, on the whole, less symptoms than the other disks.

4. A cure results when the disks are completely removed. The end result of removal of the disks is fusion of the opposing vertebrae and therefore stabilization of the spine. This obviates the necessity of fusion by bone grafts to the spine.

5. Spinal fusions by grafts are never indicated either for spondylolisthesis or for defective intervertebral disks. Their continued use means that the disks have been improperly recognized or treated, or both.

Johns Hopkins Hospital.

ONE STAGE COMBINED RESECTION OF THE RIBS AND SPINAL FUSION FOR SEVERE SCOLIOSIS

WILLIAM H. BICKEL, M.D.

JOHN J. HINCHEY, M.D.

Fellow in Orthopedic Surgery, Mayo Foundation
AND

O. THERON CLAGETT, M.D.

ROCHESTER, MINN.

It has long been recognized that in cases of severe thoracic scoliosis the posterior part of the thorax on the convex side of the scoliosis is unduly prominent owing to the vertebral rotation with corresponding deformity of the ribs. Although arrest of the progress of the scoliosis is the prime purpose of therapy, a procedure which, in addition, eliminates this prominence is preferred by the patient. Failure to correct such deformity frequently causes dissatisfaction. Buchman¹ in 1930 reported a case in which he performed resection of the ribs for thoracic deformity owing to the patient's insistence on cosmetic improvement, although the progression of the scoliosis had been halted for a year by a spinal fusion.

Accordingly, in 1927 Whitman² proposed resection of the prominent ribs and the use of the resected portions of the ribs as bone grafts to fuse the curved spinal column in such cases. A graft from some other region rather than a Hibbs procedure is required, since the concave side of the scoliosis is almost inaccessible, the laminae and facets being rotated, twisted and overhung by the spinous processes and distorted convexity of the ribs. In some instances operation was done in two stages owing to the general poor condition of the patients and the length of the procedure. He reported 9 cases in which successful results were obtained with the procedure. In discussing Whitman's work, Campbell mentioned noting an increase in expansion of the thorax after he had employed a similar procedure.

From the Section on Orthopedic Surgery, Mayo Clinic (Dr. Bickel), and the Division of Surgery, Mayo Clinic (Dr. Clagett).

Read before the Section on Orthopedic Surgery at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

1. Buchman, Joseph: Cosmetic Result in a Case of Marked Scoliosis with Rotation of the Ribs Treated by Convex Frame, Spine Fusion and Rib Resection, *Am. J. Surg.* 8: 1081-1083 (May) 1930.

2. Whitman, Armitage: A Variation in the Operative Treatment of Structural Scoliosis, *J. A. M. A.* 89: 2159-2161 (Dec. 24) 1927.

Cleveland³ has stated that thoracoplasty itself may produce scoliosis toward the side of the resection. Wenger⁴ said that resection of ribs has little influence in producing scoliosis if the transverse processes of the vertebrae are not injured or removed. According to Clagett,⁵ careful attention to the integrity of the spinal musculature during thoracoplasty will prevent lateral curvature of the vertebral column.

The cases in which operation is performed are usually the ones in which efforts at conservative treatment have not been attended with success and the scoliosis has become progressively worse. Associated with the scoliosis is the gross distortion of the wall of the thorax. If the disease is allowed to proceed without any form of operative treatment, symptoms referable to the back and an unsightly deformity usually will develop. Since the majority of the patients are adolescent girls, the most frequent complaint mentioned is the deformity.

Fig. 1.—Diagrammatic sketch showing split ribs in place in prepared bed; inset shows incisions most frequently used

If the deformity can be corrected to some extent and if the scoliosis can be arrested by spinal fusion by the same procedure without undue risk to the patient, we can see no objection to this type of surgical procedure.

Resection of the ribs and the use of the removed segments of the ribs to fuse the spinal column has been performed in 11 cases in the past thirteen years at the Mayo Clinic; in 8 of these cases the operation has been done in the past four years. For seven to ten days before operation the patient is kept on a curved hyperextension frame the apex of which corresponds to the point of greatest convexity of the spinal curve. During this period traction of 6 pounds (2.7 Kg.) is applied to the head and feet. Resection of the ribs and spinal fusion are done as a single procedure, the former

by a thoracic surgeon and the latter by an orthopedic surgeon, the two having previously collaborated in deciding on both the number and the portion of ribs to be resected and the number of vertebrae to be fused. Originally a curved incision over the spinal column

Fig. 2—*a*, idiopathic scoliosis with long sweeping curve in case 1 prior to operation, *b*, progressing spinal fusion from fourth thoracic to the third lumbar laminae and spinous processes, some improvement has occurred in the deformity

was used, but this was abandoned as the resulting scar serves to accentuate the deformity. The procedure can be carried out through one long straight incision over the spinal column; but more frequently two parallel incisions are made, one over the convexity of the ribs and one over the region to be fused—as there is less

Fig. 3—Frontal view of patient 1: *a*, before operation, *b*, six months after operation

likelihood of disturbing the integrity of the spinal musculature. The ribs are resected subperiosteally throughout the extent of the thoracic prominence. The resected portions are then split lengthwise and placed in an overlapping double row along the whole extent of the concave side of the scoliosis curve next to denuded

laminae and spinous processes from which cortical and cancellous bone have been reflected laterally (fig. 1). Their own curve corresponds strikingly to that of their spinal bed and they may be partially broken, like a greenstick fracture, to obtain closer coaptation. They are held in place by closure of the overlying muscles and fascia. No graft from any other source is necessary; there is always more than enough bone from the resected portions of the ribs. Immediately after operation the patient is kept on a straight Bradford frame for two weeks, being turned from the supine to the prone position and vice versa at regular intervals. The use of the previously mentioned traction and the hyper-extension frame is then resumed for four weeks; a plaster body jacket then is applied by using a Goldthwaite frame. The patient is permitted to be up and around for a week. The cast then is removed and a new one is applied from the occiput and chin to include the iliac crests. The patient is held in upright suspension during application of the cast. The second cast is worn for approximately four months and then it is

When the patient returned to the clinic for examination on Nov. 6 and again Dec. 17, 1935 the spinal column apparently was solidly fused and examination revealed that the deformity was greatly improved (figs. 2 *b*, 3 *b*, 4 *b* and 5 *b*). Her subsequent course has been entirely satisfactory and no progression of the deformity has taken place in the past nine years.

Fig. 5—Posterior view of patient 1 with back flexed to accentuate thoracic deformity. *a*, before operation; *b*, six months after operation.

CASE 2.—A woman aged 22, seen first at the clinic on Aug. 12, 1942, had noted a curvature of the spinal column for the past nine years. Progression of the curve was thought to have occurred two years previously, but the patient had not complained of tiredness and aching in the back on overexerting herself. There had been some increase in the prominence of the left hip, and it was thought by the examining physician that the lumbar curvature was increasing. She presented a gross right thoracolumbar scoliosis with a single sweeping curve (figs. 6 *a*, 7 *a* and 8 *a*).

Operation was performed on Feb. 4, 1943 after a preliminary period of traction. Prominent portions of the sixth to the

Fig. 4—Lateral view of patient 1: *a*, before operation; *b*, six months after operation.

replaced by a corset or Taylor brace, which is used for six months. At this time such activities as swimming and breathing exercises are begun. The brace or corset is gradually discarded and there is a progressive return to normal activity.

REPORT OF CASES

We shall report cases which are representative of the 11 cases in this series:

CASE 1.—A girl aged 15 years, seen first at the clinic on May 21, 1935, had had a minor fall three and a half years previously, and a deformity of the spinal column had been noted subsequently. She had a severe thoracolumbar scoliosis on the right side with great deformity of the ribs (figs. 2 *a*, 3 *a*, 4 *a* and 5 *a*). On May 30, 1935 portions of the seventh to the tenth ribs inclusive were removed and rib grafts were inserted from the fourth thoracic lamina and spinous process down to include the second lumbar lamina and spinous process on the concave side of the curve. Her postoperative course was uneventful and she was dismissed from the hospital in fifty-two days wearing the usual cast applied in suspension, which included the chin and occiput and extended well onto the iliac crests.

Fig. 6—Idiopathic scoliosis in case 2. *a*, before operation, *b*, solid fusion of grafts from the fifth thoracic to the third lumbar laminae and spinous processes one year after operation; there has been no progression of the scoliosis.

ninth ribs inclusive were resected on the right side and used as grafts for the prepared laminae and spinous processes of the fifth thoracic vertebra to the third lumbar vertebra. The postoperative course was marred by some respiratory difficulty because of a pleural effusion on the twenty-sixth postoperative day. Eight hundred cc. of serosanguineous fluid was aspirated

on this day and 600 cc. on the following day, with rapid subsidence of symptoms until she was dismissed from the hospital wearing a cast on the seventieth day after her admission.

The patient returned to the clinic for an examination on July 20, 1943. The cast was removed and a brace applied. On Feb 11, 1944 she was examined again and roentgenograms

Fig 7—Posterior view of patient 2 a, before operation, b, one year after operation

and photographs were made (figs. 6b, 7b and 8b). She had no symptoms and had increased her activities to include swimming and dancing. She was told to assume normal activity gradually. In a recent letter she said that her progress has been satisfactory.

CONSIDERATION OF CASES

In this group of 11 cases the characteristic features corresponded to those generally reported.⁶ Ten of the patients were females and 1 was a male; their ages

Fig 8—Appearance of patient 2 a, before operation, showing rib deformity with spinal column flexed, b, improvement in the deformity of the thoracic cage one year after operation

varied from 11 to 22; the average age was 16 years. The scoliosis had been noticeably present for from one to thirteen years; the average duration was six years. In 10 cases the scoliosis was on the right side; in 1

case it was on the left. In 3 cases the scoliosis was congenital (fig. 9) and in 1 case it occurred after poliomyelitis. No known cause could be determined in the other cases. Previous therapy, which had included braces, casts and exercises and manipulation, had failed to halt the progress of the scoliosis. In 2 cases no treatment had been employed (table 1).

The number of involved ribs ranged from three to six. Usually, from 2 to 5 inches of the respective ribs was resected. The amount of the ribs resected varied with the position of the rib as related to the scoliosis; it decreased as the distance above or below the apex of the curve increased. Portions of the first, second or twelfth ribs never were resected; portions of the third and eleventh ribs were resected in only 1 instance. The number of vertebrae fused ranged from eight to fourteen—the whole dorsal vertebral curvature was grafted in each instance. Lumbar vertebrae were included in the grafting procedure in all but 2 cases (table 2).

TABLE 1.—Clinical Data

Case	Age, Yrs.	Sex	Etiology	Direction of Thoracic Curvature	Known Duration of Scoliosis, Yrs.	Previous Therapy

7	Sixth to ninth	4	Fifth thoracic to second lumbar	10
8	Fourth to seventh	4	Second thoracic to second lumbar	13
9	Fifth to ninth	5	Fifth thoracic to first lumbar	9
10	Sixth to eleventh	6	Second thoracic to third lumbar	14
11	Fourth to eighth	5	Third thoracic to third lumbar	13

In 3 cases it was deemed advisable to administer transfusions of blood as a supportive measure. One thousand cc. of blood was transfused in 2 cases and 500 cc. in the other case. In 3 cases the operation was followed by pleural effusion. In each of these cases the effusion was situated on the side of the rib resection. In 1 a massive effusion occurred the fourth week after operation. Aspiration of 800 cc. of fluid relieved the symptoms; thereafter the effusion was minimal, until it disappeared the following week. In another case the effusion appeared on the twelfth day after operation and persisted until the fifth week before it subsided. The patient had some slight difficulty in respiration and a low grade fever during this period. In the third case there was slight respiratory distress from the fifth to the seventh day and a slight pleural effusion was noted; improvement then took place spontaneously. In these cases there was no other complication and none of the patients died. The patients withstood a rather extensive operation very well, and in no case was it necessary to interrupt the procedure or have concern over

6. End Result Study of the Treatment of Idiopathic Scoliosis: Report of the Research Committee of the American Orthopaedic Association, J. Bone & Joint Surg. 23: 963-977 (Oct.) 1941.

the patient's condition. If after the resection of the ribs further operation is not advisable, the ribs can be preserved by refrigeration and used at a subsequent operation for grafting of the spinal column.

Results.—In this series of 11 cases follow-up data were obtained for nine months to twelve years after operation. In 3 cases the operation has been done within the past year. In all cases fusion was solid at the end of six to nine months. In 3 cases in which operation has been performed rather recently it cannot be stated definitely that the deformity will not progress; however, improvement had occurred at the time this paper was written. In 1 case a very slight increase in the spinal curvature has taken place since operation. In 1 case, in which operation was performed a year and eight months ago for congenital scoliosis with a single sweeping curve, there has been a definite increase in the scoliosis. Fusion was accomplished from the second thoracic to the second lumbar vertebrae and the recent breakdown is apparently in the lower three lumbar vertebrae. Another fusion operation is being contemplated. In the other cases the deformity has remained stationary or has improved slightly.

Satisfaction concerning the cosmetic end results was expressed in all cases. In 1 case, however, the vertebral rotation was so extreme that the vertebrae were just under the deformed ribs and their transverse processes caused the scoliotic prominence in the main to be retained after resection of the ribs. Consequently,

six months after operation extensive regeneration had occurred and the new portion conformed to the corrected contour of the thoracic wall (fig. 10). Clinically, the thoracic cage is rigid after about six months.

COMMENT

This paper is based on 11 cases of scoliosis in which resection of ribs and immediate spinal fusion was performed to correct the deformity of the thoracic wall and arrest the scoliosis. It is felt that this procedure is worthy of more extensive use and has a definite place in the treatment of severe scoliosis.

ABSTRACT OF DISCUSSION

DR. EDWARD L. COMPERE, Chicago: My experience in the use of this method has not been wide. I have reviewed records of 9 patients in whom rib resection and fusion of the spine with the resected ribs, in the treatment of severe scoliosis, had been done by me or by one of my associates. Five were operated on within the past two years. This procedure has a definite place in the field of orthopedic surgery. However, certain hazards should be considered. Bissgard, while on the staff at the University Hospital in Ann Arbor, reported a series of cases of scoliosis that developed following rib resections for thoracoplasties. In Bissgard's patients the convexity of the spine was toward the side from which the ribs had been removed. The ribs are of importance in maintaining the shape of the thorax and they act as struts to support the spine itself. Especially are they important in growing children. It is a mistake to remove ribs in young children. The growing child who has lost support from the ribs may develop a progressive curvature in spite of the fact that the resected ribs have been used to fuse the spine. In cases in which I have used ribs for resection I have not attempted to correct the curvature beforehand. I have selected for this operation older patients whose deformity was so advanced that it seemed futile to attempt correction. In the drawing by which the authors illustrated the technic of their operation the ribs had been resected at a point 2 or 3 centimeters from their vertebral articulations. When the vertebral ends of the ribs are left long they may protrude so sharply that they create a ridgelike projection that is fully as objectionable as the original deformity. In my opinion this operation should be carried out in two or more stages if the extent of the fusion must include more than six vertebral segments.

DR. DANIEL H. LEVINTHAL, Chicago: I have had no personal experience with this method because I have almost always been contented to use large, long, either single or double tibial grafts, with the addition of multiple chip grafts, especially in the area between the curvature (if any remains) and the straight graft. In my service at Cook County and Michael Reese hospitals we start saline and glucose and give 500 to 1,000 cc. of whole blood during the operative procedure. We use two surgical teams. These two teams can work at the same time. The tibial graft can be removed at the same time that the bed is being prepared. Most patients, despite arrest or correction of the scoliosis, feel that since they have submitted to extensive surgery the rib and scapular convexity should have been corrected. Since most of the patients are females, many of them object to the resultant scars. I wonder how many of the authors' patients complained about the two long scars. I should like to ask whether after rib resection the inferior angle of the scapula has been sutured downward and medially in an effort to correct its winged position and in an effort to pull that portion of the shoulder girdle posteriorly to a corrected position. I have always made it a point in the preoperative discussion with the parents to state that I will attempt to correct or arrest the scoliosis, and I mention that the anterior projection of the shoulder—usually it is the right shoulder—and the convexity of the vertebrae (the so-called razor back deformity) will remain. One point which has not been mentioned is the opposite convexity of the left anterior ribs with projection of the breast and ribs forward. I am wondering whether that left anterior projection was increased when the circumference of the rib cage was interrupted by the multiple rib resections.

Fig. 9.—Structural scoliosis caused by congenital hemi-vertebra (tenth thoracic).

Fig. 10.—Idiopathic scoliosis: a, before operation, showing deformity of ribs; b, regeneration of resected ribs on the right side six months after operation.

in this case less improvement than expected was obtained. Roentgenographic examination of the ribs six weeks after resection revealed early regeneration of the resected portions from the remaining periosteum;

DR. W. H. BICKEL, Rochester, Minn.: The literature is particularly devoid of any reports on these cases, and it is only by an accumulation of various series of cases that we shall be able to form a definite opinion as to the value of this procedure. The amount of rotation which takes place in a spine after fusion is a rather moot question. If the fusion is solid it is difficult to see how the remaining rib nubbins can cause difficulty. One patient in our series did complain of tenderness over the projecting portion of the remaining rib. Dr. Levinthal mentions saving the transverse processes in the resection of the rib. I think that has been emphasized in the literature by those performing thoracoplasties. They say if one does not damage the transverse process no scoliosis will develop. Dr. Clagett feels that the integrity of the spinal musculature is more important than the conserving of the transverse processes. That is one of the reasons for the two incisions we have been using. In our cases there has been no apparent increase in the actual deformation of the thoracic cage. It seems reasonable to me to assume that if one decreases the deformity in the posterior ribs on the opposite side the anterior deformity will cave in and be less prominent following the resection of the ribs. I think our photographs and the observations of these patients bear out that point. There have been no recorded complaints regarding the scars. Of course, with midriff bathing suits, some complaints may ensue in the future. We have never used scapular fixation. It has been our method to resect the ribs high enough so that the scapula will not be pushed out, rather than to try to fix the scapula over bulging ribs posteriorly.

THE PREVENTION AND ATTENUATION OF INFECTIOUS HEPATITIS BY GAMMA GLOBULIN

PRELIMINARY NOTE

JOSEPH STOKES JR., M.D.

PHILADELPHIA

AND

CAPTAIN JOHN R. NEEFE

MEDICAL CORPS, ARMY OF THE UNITED STATES

Infectious hepatitis (epidemic hepatitis, infective hepatitis) has been stated to be one of the most important diseases of the present war.¹ It has also been a serious problem in civilian populations throughout the world. Owing primarily to the lack of knowledge concerning the etiologic agent and its mode of transmission, adequate methods of prevention and control have not as yet been developed. It is our purpose in this preliminary report to present data which suggest that gamma globulin² from large pools of adult human serum may be effective in the control of certain epidemics of this disease.

Parenteral injections of homologous blood products (whole blood, pooled plasma or serum, pooled measles and mumps convalescent plasma, and so on) have occasionally been followed by hepatitis. These blood products have usually been derived from single individuals or, in the case of pools, from relatively small numbers of young adults. The frequency with which small pools contain a "hepatitis producing" agent suggests that such an agent might be expected in large pools with even greater frequency. Yet several thousand injections of gamma globulin (used for prevention and attenuation of

measles), prepared from large pools of adult plasma, have not been followed by hepatitis. It has been shown experimentally that certain virus agents, added to plasma which does not contain their specific neutralizing antibodies, are not inactivated by the process of fractionation and subsequently can be demonstrated in the globulin fraction II + III.³ Thus the absence of hepatitis following the use of gamma globulin is not necessarily explained by inactivation of the causative agent by the process of fractionation of plasma. The neutralization of the "hepatitis producing" agent by antibodies in gamma globulin would offer, however, a possible explanation of the apparent absence of hepatitis following the injections of gamma globulin.

Because the evidence thus far available suggests that the virus agent responsible for epidemic or infectious hepatitis is present in the blood during the preicteric and early icteric phases of the disease, it seemed reasonable to postulate that such neutralizing antibodies in gamma globulin might possibly be effective in aborting or in attenuating this disease if administered during the incubation period or preicteric stage. The relatively long incubation period of infectious hepatitis and the delayed onset of the icteric stage are time factors which would facilitate the use of gamma globulin for this purpose. These theoretical and factual observations led to the use of gamma globulin in an extensive epidemic of infectious hepatitis that occurred during August and September 1944 in a summer camp for boys and girls.

The epidemic, details of which will be reported elsewhere, began on Aug. 1, 1944 and by August 14, when we were notified of its existence, approximately 80 persons had developed hepatitis. The occurrence of new cases on the 15th and 16th of August suggested that the entire camp population had been or would be exposed to the causative agent and that many others of the group could be expected to develop the disease. The situation seemed favorable, therefore, for a critical test of the hypothesis that gamma globulin might include specific antibodies capable of inactivating, partially or completely, the causative agent of infectious hepatitis. Using an arbitrary intramuscular dosage of 0.15 cc. per pound of body weight, sufficient gamma globulin⁴ was available for the injection of 53 persons. Of 159 well boys between the ages of 6 and 15 living under the same environmental conditions in the boys' camp, 29 were injected with globulin, leaving 130 as controls. Of 132 well females between the ages of 6 and 30 living in the girls' camp, 16 were injected with globulin, leaving 116 as controls. Eight other men between the ages of 16 and 40 from miscellaneous camp groups also were injected. As expected, many additional cases of hepatitis developed during the five weeks following the globulin injections. In the accompanying table the incidence of hepatitis in the injected groups is compared with that in the control groups. In the discussion of these data the term hepatitis includes both icteric and nonicteric cases. Approximately one third of those who became ill with the typical symptoms failed to develop jaundice. Liver function studies on representative nonicteric cases confirmed the diagnosis of hepatitis without jaundice. The data on cases of hepatitis with jaundice are shown separately because they were usually more severe and of longer duration than the nonicteric cases. The boy and girl groups also

4. The gamma globulin employed in this study (lots 12 II GI L329 and II GI L371) was prepared by the Harvard Plasma Fractionation Laboratory. Lot 12 II GI L329 was an experimental lot prepared under conditions slightly different from those employed in the preparation of the standard fractions being distributed for measles prophylaxis.

have been presented separately in the table because the course of the epidemic suggested that these two groups were not exposed to the disease at the same time, a fact which is of importance in the interpretation of the findings. The results in the 8 injected males from the miscellaneous camp groups are not shown separately in the table because of the lack of a satisfactory control group for comparison. However, these have been included in the data referring to the entire camp group which show the results in the total injected group; the controls for this group include, in addition to the boy camper and female control groups, those in miscellaneous camp groups who were well at the time of the globulin injections. Such a combination is permissible because the final incidences in all the camp groups indicate that all were eventually exposed to the disease. The statistical significance of these data was tested by the chi square method.

The results show that the incidence of hepatitis in the groups injected with gamma globulin was significantly lower than in the control groups. In respect to the boy camper group, 13.3 per cent of those injected developed hepatitis as compared with 69 per cent of the controls. Overt jaundice appeared in 46 per cent of the controls, but this was not observed in any of those who received globulin. In the female group, hepatitis

results were obtained in the boy camper group. It is probable that most of this group received globulin earlier in the incubation period than did the girls, because the epidemic began in the boys' camp approximately a week later than in the girls' camp. The apparent difference in the effectiveness of gamma globulin in these two groups would seem to be satisfactorily explained on this basis.

The results indicate, therefore, that gamma globulin is capable of preventing or attenuating infectious hepatitis when administered to exposed persons during the incubation period of the disease. They also suggest that the best results are obtained when the globulin is injected early in the incubation period. Gamma globulin thus offers promise of being of great value in the prevention and control of other epidemics of infectious hepatitis, and, since no other satisfactory methods for the control of this disease have been developed, further trials of gamma globulin in such epidemics seem definitely indicated. The effect of gamma globulin in infectious hepatitis is similar to that of its use in measles.⁵ In addition to its preventive value in measles, globulin is often of therapeutic value if injected soon after the onset of the initial symptoms; it seems possible that gamma globulin also might be of therapeutic value in infectious hepatitis if administered early

Effect of Gamma Globulin in Infectious (Epidemic) Hepatitis

Group and Age Ranges	Status	Number	Hepatitis		Hepatitis with Jaundice		Chi Square *	
			Number	Per Cent	Number	Per Cent	Hepatitis	Jaundice
Boy campers (6-15)	Injected with globulin	29	4	13.3	0	0	29.4	21.7
	Controls	130	90	69.0	60	46		
Females (6-30).....	Injected with globulin	16	3	18.7	3	18.7	16.59	4.04
	Controls	116	82	70.6	52	45		
Entire camp group (3-40)	Injected with globulin	53	11	20.8	3	5.7	37	27.5
	Controls	278	185	67.0	125	45		

* Except for the test for the incidence of hepatitis with jaundice in the female group, chi square values computed by the method of the four fold independence table indicate that such results would be expected by chance less often than one in a thousand. For the one exception, however, the probability is less than one in twenty trials.

occurred in 70.6 per cent of the controls but in only 18.7 per cent of the injected group. Overt jaundice developed in 45 per cent of the controls but in only 18.7 per cent of those injected. In terms of the combined groups, representing 53 persons injected with globulin and 278 controls, hepatitis occurred in 67 per cent of the controls but in only 20.8 per cent of those injected. Of the 53 persons receiving globulin, not one developed visible icterus of the skin. However, 3 of the 16 girls who received globulin developed scleral icterus, which, however, persisted for only four, five and seven days respectively. The average duration of icterus in the 34 controls for whom complete data are available was 14.2 days. These observations suggest that the effect of gamma globulin in the 3 girls was an attenuation of the disease.

The onset of hepatitis in the 11 persons who received gamma globulin occurred during the first ten days after the globulin had been injected. No additional cases occurred among the injected group after this time. However, cases continued to appear among the controls for thirty-two days after the date of the globulin injections. This would suggest that the administration of gamma globulin late in the incubation period resulted in attenuation, rather than prevention, of the disease. However, the data indicate that the disease was entirely prevented in some cases, this probably occurring in those who received the globulin early in the incubation period. This is supported by the fact that the best

in the preicteric period. For this reason the use of gamma globulin as a therapeutic measure in early hepatitis would also seem to be worthy of trial.

SUMMARY

During an epidemic of infectious hepatitis in a summer camp for boys and girls gamma globulin was injected intramuscularly into 53 of 331 persons who at the time showed no signs of the disease. The results, which are statistically significant, indicate that gamma globulin is capable of preventing or attenuating infectious hepatitis when administered to exposed persons during the incubation period of the disease. This effect is comparable to that observed with the use of gamma globulin in measles. Although the data suggest that the best results are obtained when the globulin is injected early in the incubation period, it seems possible that, as in measles, it may also be of therapeutic value if given early in the preicteric stage of hepatitis. The results obtained in this epidemic are sufficiently encouraging to warrant further trials of gamma globulin in the control of future epidemics of this disease. This is especially desirable because no other effective control measures have as yet been developed.

TRANSMISSION OF PRIMARY ATYPICAL PNEUMONIA TO HUMAN VOLUNTEERS

COMMISSION ON ACUTE RESPIRATORY DISEASES

FORT BRAGG, N. C.

Etiologic studies of primary atypical pneumonia have been described in several recent publications.¹ It has been shown that bacteria,² rickettsias,³ fungi⁴ and viruses, particularly those of the psittacosis group,⁵ may produce the syndrome of atypical pneumonia. No etiologic relationship to these known agents, however, has been demonstrated in the majority of cases, and the assumption has been made that an unknown virus is the causative factor.

Various pneumotropic agents have been isolated in animals,⁶ but confirmation of the relationship of these agents to the human disease has been lacking. During the past three years, extensive animal experimentation has been undertaken by the Commission on Acute Respiratory Diseases.⁷ Sputums, throat washings and blood obtained from patients, and pathologic material from fatal cases, have been utilized. Various routes and methods of inoculation have been employed. No bacteria or viruses bearing a direct etiologic relationship to the human disease have been isolated in the developing chick embryo, in chickens, doves or Java rice birds and in seven mammalian species. In view of these negative results, attempts have been made to transfer primary atypical pneumonia in man. Vance, Scott and Mason⁸ failed to establish the infection in 7 volunteers inoculated intranasally with filtered pooled sputum and nasal washings.

From the Respiratory Diseases Commission Laboratory, Regional Hospital, Section 2, Fort Bragg, North Carolina.

This investigation was supported through the Commission on Acute Respiratory Diseases, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army, Preventive Medicine Service, Office of the Surgeon General, United States Army, and by grants from the Commonwealth Fund, the W. K. Kellogg Foundation, the John and Mary R. Markle Foundation and the International Health Division of the Rockefeller Foundation to the Board for the Investigation and Control of Influenza and Other Epidemic Diseases for the Commission on Acute Respiratory Diseases.

Members and professional associates of the Commission on Acute Respiratory Diseases are John H. Dingle, Major, M. C., A. U. S., Director; Theodore J. Abernethy, Major, M. C., A. U. S.; George F. Badger, Captain, M. C., A. U. S.; Joseph W. Beard, M.D.; Norman L. Cressy, Major, M. C., A. U. S.; A. E. Feller, M.D.; Irving Gordon, M.D.; Alexander D. Langmuir, Captain, M. C., A. U. S.; Charles H. Rammelkamp, M.D.; Elias Strauss, Captain, M. C., A. U. S., and Hugh Tatlock, 1st Lieutenant, M. C., A. U. S.

The Commission was assisted by the technical staff of the laboratory: Pfc. Alexander Adler, Ruth Chase, T/5 D. G. Foltz, Corp. M. H. Kaplan, Elizabeth Krakauer, T/5 G. J. Leuty, Dorothy Mickie, Second Lieutenant W. A. Mickle, Sn. C., Josephine P. Neely, Barbara A. Mulliken, First Lieutenant T. J. Oliver, Sn. C., First Lieutenant R. L. Robinson, Sn. C., and Irene Salamandra.

These studies were made possible by the cooperation of the administrative staffs of Selective Service, Camp Operations Division, and the National Service Board for Religious Objectors, the American Friends Service Committee, Brethren Service Committee and the Mennonite Central Committee. Cooperation and assistance were given by Brig. Gen. H. C. Coburn Jr., M. C., Col. J. C. Williams, M. C., Col. R. C. Tatum, M. C., Lieut. Col. W. B. Daniels, M. C., Lieut. Col. F. K. Herpel, M. C., Lieut. Col. F. J. Pohle, M. C., Lieut. Col. A. Blumberg, M. C., Capt. D. G. Walker, M. C., Capt. Michael Levin, M. C., and Capt. B. L. Heffner, M. C.

First Lieut. Clare B. Kwash, A. N. C., Second Lieut. Catharine E. Hammond, A. N. C., and Mrs. Catherine Kruse rendered invaluable service as nurses. T/4 Albert Aan gave material assistance as x-ray technician. Mr. O. E. Stone acted as assistant director of the C. P. S. unit throughout the course of the experiments. Messrs. J. H. Burrows, R. F. Landis, M. H. Leffel, D. H. McBee, W. M. McMillan, D. W. Mott, P. S. Olmsted, Edward Outland and T. F. White voluntarily served as attendants.

The members of the Commission are grateful to the volunteers themselves, without whom these experiments would have been impossible. 1. Dingle, J. H.; Abernethy, T. J.; Badger, G. F.; Buddingh, G. J.; Feller, A. E.; Langmuir, A. D.; Rueggesser, J. M., and Wood, W. B., Jr.: *Primary Atypical Pneumonia, Etiology Unknown*, Am. J. Hyg. 59: 67-128 (Jan.), 197-268 (March), 269-336 (May) 1944. Weir,

(Footnotes continued in next column)

Our purpose in this communication is to report the successful transmission of primary atypical pneumonia to human volunteers by means of bacteria-free filtrates. Previous experiments⁹ had indicated that this syndrome could be produced in certain individuals by inoculation with unfiltered throat washings and sputums.

MATERIALS AND METHODS

Forty-two conscientious objectors, all of whom had volunteered for the experiment, were segregated in individual rooms of a hotel. Eighteen men were housed on the third floor and 24 on the second floor; the latter were separated geographically into two groups of 12 each by temporary partitions in the hallways.

Clinical, roentgenographic and laboratory examinations served to eliminate any individuals with acute or chronic, organic or infectious diseases. Rigid quarantine was maintained during the eight week course of the experiment in order to prevent chance exposure to atypical pneumonia through outside contact. Strict isolation technics were instituted and maintained by the attending staff. Food was prepared in a common kitchen and distributed on individual compartment trays. The volunteers were observed for symptoms and signs of respiratory disease on alternate days before inoculation and daily after inoculation. Frequent roentgenograms were taken. Determination of the total leukocyte and differential counts and of the erythrocyte sedimentation rate (Rourke-Ernstene method)¹⁰ were performed repeatedly. Throat cultures were taken weekly before and after inoculation. Specimens of serum were collected for serologic study at weekly intervals.

The inoculum consisted of throat washings and sputum collected from 6 cases of atypical pneumonia produced in a previous experiment by inoculation of untreated and filtered throat washings and sputums from cases in a military hospital. Each of the experimentally

produced illnesses had the characteristic of primary atypical pneumonia. During the course of their disease, all of the donors developed cold agglutinins to group O human red cells. The throat washings and sputums were pooled in proportion of 1 part of sputum to 5 parts of throat washings. Approximately one third of this pooled material was filtered through sintered glass and Seitz filters, another third was autoclaved at 15 pounds pres-

tion by means of an atomizer and vaporizer.¹¹ A tank of nitrogen was used as a source of pressure to vaporize approximately half of the inoculum given each man.

RESULTS

In the accompanying table are summarized the number and character of illnesses resulting from the various types of inoculum. Three patients receiving filtered

Fig. 1 (case 146).—Appearance of lungs, September 14.

Fig. 2 (case 146).—Appearance of lungs, September 16.

Fig. 3 (case 146).—Appearance of lungs, September 30.

sure for ten minutes and the remainder was untreated. Aerobic and anaerobic cultures of the filtered and autoclaved material were sterile. Culture of the untreated material showed the following organisms: alpha, alpha and gamma streptococci, *Staphylococcus aureus*, diphtheroids and gram-negative cocci (not further identified).

inoculum (group B) and 3 receiving untreated material (group C) developed characteristic symptoms, signs and roentgenologic evidence of primary atypical pneumonia. No individual inoculated with autoclaved material (group A) was similarly affected.

Onset of disease in 3 patients in group B (filtered) occurred on the twelfth, thirteenth and fourteenth days

Fig. 4 (case 137).—Appearance of lungs, September 22.

Fig. 5 (case 137).—Appearance of lungs, September 25.

Fig. 6 (case 137).—Appearance of lungs, October 4.

Inoculations of autoclaved material were given to the first group of 18 volunteers (group A) after three weeks of isolation. Four days later a second group of 12 men (group B) were inoculated with filtered material. The final group of volunteers (group C) received untreated inoculum after a further interval of eight days. The inoculations were given outdoors. Each volunteer received a total inoculum of 10 cc. administered in three equally divided doses. The material was sprayed into the nose and throat in synchronization with deep inspira-

respectively after inoculation. Onsets occurred earlier in the 3 patients receiving untreated material (group C); 2 developed on the seventh day and 1 on the eighth day after inoculation.

The symptoms and signs observed at onset and during the course of the disease did not differ materially in the two groups. In general, illnesses were milder in patients in the "filtered" group.

¹¹ Made by the Vaponefrin Company.

Roentgenographic lesions were characteristic of those seen in moderately severe cases of primary atypical pneumonia in military and civilian hospitals. In 3 individuals single lobes were involved, in 2 patients bilateral lesions were observed, and in 1 individual all five lobes were involved in association with a critical illness. The appearance, development and regression of the pneumonic lesions in patients from both the "filtered" and "untreated" groups bore a striking similarity to those seen in the naturally occurring disease.

Cold agglutinins for group O human erythrocytes developed in the serums of 5 of the 6 cases of pneumonia. In group B (filtered), maximum titers of 128, 1,024 and 1,024 were obtained respectively on the twenty-

Two case reports are included to illustrate the clinical features of atypical pneumonia observed in individuals inoculated with filtered and with untreated material:

CASE 146, Group B (figs. 1, 2, 3 and 7).—A white man aged 26 received an inoculum of filtered throat washings and sputum. Twelve days later the patient developed hoarseness and persistent cough productive of scanty amounts of sputum. The following day malaise, sneezing, nasal obstruction and discharge and substernal pain were noted. These symptoms increased in intensity. Between the fourteenth and eighteenth days a moderate febrile illness ensued, the temperature reaching a maximum of 102.8 F. Feverishness, headache, malaise, anorexia and weakness were the most prominent constitutional symptoms present during this period. The cough became more severe and was productive of large amounts of mucopurulent sputum. A roentgenogram of the lungs on the seventeenth day showed bilateral pneumonic infiltration of the right hilus and left lower lobe. Subcrepitant inspiratory rales and rhonchi were first audible over the areas of infiltration on the nineteenth day and persisted until the thirty-first day after inoculation. Convalescence was uneventful, but minimal cough was still present on discharge.

No significant alteration of the white blood cell count or of the erythrocyte sedimentation rate occurred during the illness. *Pneumococci* types 6 and 21 were isolated from the patient's sputum; type 6 was repeatedly isolated from throat cultures prior to inoculation. Cold agglutinins in a titer of 1,024 were detected in a sample of the patient's serum on the twentieth day after inoculation.

CASE 137, Group C (figs. 4, 5, 6 and 8).—A man aged 20 was inoculated with untreated throat washings and sputum. Prodromal symptoms of illness began five days after inoculation with the development of sore throat. During the next forty-eight hours the patient noted dry cough, substernal pain and fever. Other symptoms of illness became apparent on the eighth day with the occurrence of chilliness, feverishness, headache, malaise and anorexia. The temperature rose to 102 F. and physical examination disclosed coarse rales at the right lung base. A roentgenogram of the chest (postero-anterior view only) was negative. On the ninth day frontal headache and cough became severe and the temperature rose to 104.4 F. Fine subcrepitant rales and rhonchi were detected over the right lung base. The diagnosis of atypical pneumonia was confirmed by a roentgenogram which showed minimal infiltration (right oblique view). The clinical course was subsequently severe and marked by cyanosis, tachypnea, tachycardia and cough. Oxygen therapy was given with benefit for eight days. The pneumonic infiltration spread to include all five lobes. On the fifteenth day clinical signs of improvement were apparent for the first time, and thereafter convalescence proceeded uneventfully.

Laboratory studies revealed no elevation of the leukocyte counts. There was a rise in the erythrocyte sedimentation rate to 0.7 mm. per minute on the twenty-first day after inoculation, thirteen days after onset. Cold agglutinins were demonstrated in a titer of 8,192 in a sample of serum taken on the twenty-sixth day after inoculation.

In addition to the 6 cases of atypical pneumonia there were 11 cases of minor respiratory illness (as shown in the table) distributed as follows: group A (autoclaved)

Fig. 7 (case 146).—Clinical course of patient given filtered inoculum.

Fig. 8 (case 137).—Clinical course of patient given untreated inoculum.

seventh, twenty-seventh and twentieth days following inoculation. Two patients in group C (untreated) developed maximum titers of 512 and 8,192 on the twenty-first and twenty-sixth days respectively after inoculation. A third patient did not develop cold agglutinins at any time.

A rise in titer of agglutinins for an indifferent streptococcus (Rockefeller number 344)¹² was not demonstrated in the serums of any of the 6 patients with pneumonia.

Cultures of the throat, sputums and throat washings yielded no indication of a direct etiologic relationship between any single organism or group of organisms and atypical pneumonia.

12. Thomas, L.; Mirick, G. S.; Curnen, E. C.; Ziegler, J. E., Jr., and Horsfall, F. L., Jr.: Serological Reactions with an Indifferent Streptococcus in Primary Atypical Pneumonia, *Science* 98: 566-568 (Dec. 24) 1943.

1 case, group B (filtered) 5 cases, group C (untreated) 5 cases. The illness in group A was the only instance of respiratory infection occurring in any member of the autoclaved group. He was the only volunteer, as far as could be determined, who broke isolation; on at least one occasion he descended a fire escape to converse with a member of another group who subsequently developed "suspected atypical pneumonia."

The development of these minor respiratory illnesses in 10 persons receiving filtered and untreated inoculum occurred between the first and fifteenth days of inoculation. The symptoms, physical signs, course and severity of these infections were variable. Seven illnesses were afebrile and extremely mild, with minimal symptoms and signs. Three illnesses were more severe, characterized by fever, moderate symptoms and physical signs of respiratory disease. These cases were diagnosed as "suspected atypical pneumonia" or "bronchitis resembling atypical pneumonia" because the clinical course of illness was that of atypical pneumonia, although without roentgenographic evidence of pulmonary infiltration. A complete discussion of these cases of minor respiratory illness will be made in the final report of these experiments.

Characteristics of Illness Noted in Human Volunteers Inoculated with Autoclaved, Filtered and Untreated Sputums and Throat Washings from Patients with Atypical Pneumonia

Group	Type of Inoculum	No. of Men	Result		
			Primary Atypical Pneumonia	Minor Respiratory Illness	No Illness
A	Autoclaved	18	0	1	17
B	Filtered	12	3	5	4
C	Untreated	12	3	5	4
Total.....		42	6	11	25

SUMMARY AND CONCLUSIONS

Human volunteers have been inoculated with a pool of sputum and throat washings obtained from experimentally produced cases of atypical pneumonia. Respiratory illnesses having all of the characteristic features of primary atypical pneumonia developed in 3 of 12 men receiving filtered inoculum. Similarly, 3 instances of pneumonia occurred among 12 individuals inoculated with untreated material from the same source. The infection was thus carried through two successive groups of well persons. No cases of pneumonia developed in any of the 18 men who received autoclaved inoculum.

The incubation period in the experimental disease differed with the type of inoculum. Persons receiving filtered material developed symptoms of disease between twelve and fourteen days after inoculation. The onset of illness in those inoculated with untreated material was approximately one week earlier.

The results of this experiment thus demonstrate that bacteria-free filtrates, presumably containing a virus, can induce primary atypical pneumonia in man.

Blood Transfusion in the Middle Ages.—In the Middle Ages, blood transfusion was considered a therapeutic measure to restore health. It is related that Pope Innocent VIII, in the year 1490, lay dying from that "terrible disease extreme old age," and as a last resort a transfusion from three donors was attempted in 1491, which resulted in the death of the donors without saving the Pope. Needless to say, the daring physician had to flee for his life.—Gordon, Benjamin Lee: *The Romance of Medicine*, Philadelphia, F. A. Davis Company, 1944.

INJURIES OF THE CERVICAL SPINE

ARTHUR G. DAVIS, M.D.

ERIE, PA.

Starting with the fact that the great majority of injuries of the cervical spine are in the nature of a "whip lash," and accepting the meaning of the term "whip lash" as a hyperflexion followed by spontaneous extensor recoil, the nature of a great variety of injuries of this section of the spinal column becomes understandable. The extreme mobility of the cervical spine, its known potential for pure dislocation unaccompanied by fracture and its wide anatomic departure from other sections of the spinal column seem to have made specific diagnosis of lesions in this section difficult. A number of important accretions of anatomic interpretation, diagnostic technic and therapy have occurred quite recently. Correlation of these new facts has served to clarify both the diagnosis and the treatment as well as to improve the prognosis.

TYPES OF INJURIES

Two degrees of injury are immediately separated by the severity of the accident. For convenience these will be referred to as "obvious" and "obscure." The common automobile street accident, falls from a height, diving accidents and blows striking the head sufficient to cause immediate disability and emergency rescue produce the usual obvious case. When paralytic signs or gross lesions immediately "obvious" in the x-ray film or both are present, the diagnostic problem is a simple one.

The "obscure" lesions are those confronting the physician, with pain and spasm in the neck, variable pain radiation with gradations from those of trivial annoyance to those exhibiting intractable causalgia. The question of injury, whether recent or remote, is frequently slurred over by the patient for the reason that painful symptoms do not develop until some time after, a good many times years after, the injury occurs. Special questioning on this point usually brings out the history of a definite injury days, months or years prior to the onset of disabling symptoms. The patient interprets the original fleeting symptoms as a "sprain" not worthy of medical attention. As is true in the case of the ankle, the knee, the wrist or the shoulder, the word sprain indicates a partial or complete ligamentous avulsion. When such ligamentous avulsions in other parts of the body are neglected the healing process is incomplete, leaving an elongated, weakened structure which with ordinary use continues to stretch. The cervical spine is no exception; in fact, its extreme mobility renders it peculiarly susceptible to such progressive elongations with the secondary involvement of the other components of the intervertebral joint.

FUNCTIONAL AND MORBID ANATOMY

Since the accidental force carries the weight of the head beyond the normal range of motion, knowledge of the normal limits is important. For this purpose a study of normals of different types was made (fig. 1). Nine members of the hospital staff, including both sexes from the teens to the sixth decade, of mixed slender,

stocky, short and tall types, were studied. Three attitudes were posed, in the sitting position, recording only the lateral projection at 72 inches (fig. 2):

Position 1. Relaxed—the gaze focused on a point level with the eye

Position 2. "Chin chest" position—head pushed forward to approximate the chin as near to the chest as possible in order to obtain maximum range of neck flexion

Position 3 The limit of extension

When the first lateral projection of a cervical spine shows elimination of the normal forward curvature, it must be assumed that some kind of mechanical derangement has taken place, since this is just as abnormal a finding as is bowing in the tibia

dislocating vertebra. This border then impinges on the border of the subjacent vertebra as the articular processes of the dislocating body mount the processes of the subjacent one (fig. 5).

A further continuation of the same extreme hyperflexion mechanism is indicated in figure 9, in which the dislocation is complete and the articular processes are locked.

This paper represents an analysis of 134 cases of injury to the cervical spine encountered during the last twenty-two years and treated either by myself or by my associate, Dr. C. W. Fortune. Of these 73 were of the ambulatory type and the patients came to the office for treatment. The remaining 61 were of the

Fig 1—Normal standards of neutral, flexion and extension positions just mentioned shows how universally the anterior normal curvature of the cervical spine may be expected regardless of sex, age or statural type. The second row shows what may be expected in extreme flexion passively assisted by pressing the head forward on the chest. For the purpose of a composite picture these second row figures were rotated to the vertical. A straight line joining the posterior borders of the bodies of the first and seventh cervical vertebrae illustrated in figure 3 shows the amount of curvature. The third row shows how uniform extension is regardless of type

Figure 3 illustrates the localization possible by taking a lateral view in the "chin chest" position.

A four weeks old injury with complaint of pain and spasm in the neck region with radiation down the arm is shown in figure 4.

As increasing degrees of the hyperflexion force are encountered, not only are the fibers of the capsule of the articular process ruptured but also the posterior common ligament with presumably some fibers of the annulus fibrosus. When this occurs, the pivot of motion is no longer at the juncture of the pedicle and body but shifts forward to the anterior lower border of the

"obvious" emergency type and represent admissions by ambulance to the hospital. Prior to the year 1936 elimination of the normal forward curvature was not noted. Reviewing the films in these cases, it was found that 16 of the 41 showed straightness of the entire cervical spine. Since 1936 11 out of the remaining 32 were noted as showing elimination of the cervical curvature. In 17 of these 27 cases opinions were rendered to insurance carriers or the patients themselves and it is clear that prior to 1936 the opinion was in error for the obvious reason that the significance of straightness of the cervical spine was not appreciated.

"OBSCURE TYPE"

An analysis of the 73 cases in the "obscure" neurologic group shows that the automobile head-on collision is the most prolific cause. The velocity of the car is also the velocity of the individual and his parts. Ordinarily the torso and the legs are braced at the moment of impact of the head-on collision. The extreme mobility of the cervical section of the spine permits the weight of the head to continue its forward momentum after the moment of impact. The degree of hyperflexion "whiplash" is directly proportional to the speed at the moment of collision. Any degree of injury must therefore be anticipated, from slight strain involving the tearing of a few fibers of the posterior articular ligaments, disk injuries and complete dislocations to fatal cases in which the cord is severed. It is the lesser degrees of injury which have eluded specific diagnosis. Immediately following such an accident the elastic extensor recoil mechanism provided by the static posterior cervical musculature and the ligamentum flavum is the mechanism which serves to conceal the damage which has occurred, since it effects a variable degree of reduction spontaneously. Spasm of the cervical musculature serves to avoid painful contact of the injured part; therefore the facets are not restored to their normal apposition. The entire cervical spine is held slightly forward to avoid such painful contact of the posterior articular processes. The elimination of the normal forward curvature thus produced provides the clue to the damage concealed by the spasm. If such cases are seen immediately afterward and the lateral projection shows a straight cervical spine, obviously a picture should be taken in the "chin chest" position. A great many of such cases, however, have but fleeting symptoms which disappear in a few days and the individual resumes the normal use of his head and neck. In exactly the same manner as a neglected ankle sprain, such torn ligaments heal in the long position. Normal use thereafter continues to stretch the ligaments, accounting for the increasing disabling symptoms occurring from three months to years afterward. Such neglected cases result in pain in the cervical region with variable pain radiation.

Analyzing the 73 cases from the point of view of their pain radiation, seven different syndromes become recognizable:

1. The occipital syndrome.
2. The third and fourth cervical root syndrome.
3. The fifth cervical root syndrome
4. The sixth cervical root syndrome.
5. The seventh cervical root syndrome
6. The precordial syndrome
7. The syndrome of the long thoracic nerve

In referring to the root numbers it will be remembered that the number of the root corresponds with the space above the vertebra of the same number. The occipital syndrome associated with lesions of the axis or atlas is recognized by pain radiating up one or both sides of the occipital region together with limitation in

nodding, rotation and tilting of the head or wry neck. The third and fourth cervical root syndrome is associated with muscle spasm and pain along one or the other lateral angles of the neck. In the fifth cervical root syndrome the pain radiates over the shoulder region, in the sixth to the radial side of the hand and in the seventh to the radial side of the hand, including the index and in some cases the middle finger. The syndrome of the long thoracic nerve has been seen twice in this series; both cases showed "winged" scapula,

Fig. 2—Functional anatomy. For this purpose arbitrary points were selected on each vertebra and lines extended to visualize the movement. *A* is in relaxation with the eyes horizontal, position 1. Note that the posterior lines are nearly parallel, evenly spaced and horizontal (in balance). *B* shows the "chin chest" position, and the degree of deviation of the lines is variable. The sixth and seventh remain nearly horizontal. The greatest range is seen between the fourth and the sixth. Note that in *C* the convergence of the posterior lines is maximal between the third and the sixth. In terms of the "whiplash" mechanism, it will be seen that the sixth and seventh form the stock of the whip and the upper vertebrae the lash. The movement indicated by the anterior lines is best explained by the movement involved in the shift of the nucleus pulposus, the approximation of the anterior edges of the vertebrae in *B* being consistent with the convergence of the lines, just as the divergence of the lines in *C* is accompanied by an approximation of the posterior edges of the body.

Fig. 3—Localization of lesion. Four years before, the patient sustained an electrical shock. During the effort to withdraw his hand from contact with wires, a severe "throw" of the head occurred. He experiences occasional pain and stiffness in the neck with shoulder radiation, which he relieves posturally. Note the straightness of the spine in *A* also forward tilting of the body as measured by the posterior border of the fourth. *B* 1 shows the excursion of the posterior edge of the superjacent articular process from the subjacent one. *B* 2 shows the separation of the posterior edges of the body and the shifting of the nucleus to account for this spread. *B* 3 shows the approximation of the anterior edges, and *C* shows how hyperextension restores all normal relationships.

complete paralysis of the serratus anterior and roentgenographic evidence of injury at the seventh cervical level. Horner's syndrome was not observed in any case in this series.

In the case of disk protrusion, the signs are considerably more definite than in the case of pure luxation

without protrusion. In the 2 instances, however, they cover the same areas. Mixter and Barr,¹ McKenzie,² Oppenheimer,³ Semmes and Murphey,⁴ Spurling,⁵ Stookey⁶ and Stuck⁷ have all pointed to syndromes associated with disk protrusion showing sharply deline-

to the number of the nerve root. Figure 7 shows involvement of the fourth nerve root. Figure 8 illustrates a typical case of sixth root radiation.

DIFFERENTIAL DIAGNOSIS

With the clue to mechanical derangement established by the fact that the cervical spine exhibits a straight line in the lateral projection, differential diagnosis depends on a proper correlation of x-ray appearances with nerve root radiation. Semmes,¹ Spurling⁵ and Oppenheimer⁸ have noted straightness of the cervical spine in disk lesions. Watson-Jones¹⁰ also makes note of straightness as an incident in "sprain" of the cervical spine. Oppenheimer⁸ notes lesions of the articular processes and encroachment on the intervertebral foramina due to spurs surrounding the intervertebral disk. The scalenus syndrome has been mentioned.¹¹ This obviously is not associated with straightness of the cervical spine. Pure muscle ruptures are not ordinarily painful beyond the first two weeks.

A specific diagnosis, therefore, rests on the correlation of positive x-ray findings corresponding to a definite level of root radiation as described. Spurling⁵ has shown that disk protrusions can be visualized with pantopaque. He also finds that compression downward of the head on the side of involvement produces pain in one of the root areas mentioned. Careful roentgenography in the sitting relaxed position with the eyes horizontal and the "chin chest" position and bilateral oblique films to show the intervertebral foramina will frequently reveal a lesion of one or other of three kinds:

1. Luxation of the posterior facets.
2. Narrowing of the intervertebral space.
3. Lesions encroaching on the intervertebral foramen.
4. Combinations of any two or all.

Fig. 4.—One month old luxation injury. The separation of the posterior margins of the articular processes between the fifth and sixth vertebrae is easily demonstrated with flexion (compare 2 with 1). The wide separation as indicated in 4 as compared with 3, confirms this conclusion. The patient complained of pain over both shoulders, which disappeared with the hyperextension collar.

ated areas of sensory and motor change. Semmes,⁴ Oppenheimer⁸ and Nachlas⁹ point to the association of precordial pain with sensory changes involving the radial side of the hand, while in other contributions reference is not made to the precordial pain of an anginoid type.

It is important to eliminate the scalenus syndrome in all chronic cases involving pain radiation to the hand. Figure 4 illustrates the areas involved according

Fig. 5.—Disk lesion associated with fracture. Note the anterior projecting fragment of the seventh cervical as well as the contacting exostoses of the posterior edges of the sixth and seventh cervical, the narrowing of the intervertebral space, also that no change is noted in the narrowing of the articulations. Pain of a causalgia type radiated to the posterior articulations. Pain of a causalgia type radiated to the finger tips of the right hand. There was also paralysis of the serratus anterior.

"OBVIOUS" LESIONS

No attempt will be made to outline specifically diagnosis and treatment of the frank outspoken fracture dislocations with or without paralysis for which imme-

diate definitive treatment is indicated except to state rules of procedure in the handling of such cases. Here also recent acquisitions in several departments have resulted in revisions of approach, diagnosis and treatment.

Fig. 6—A case of typical fourth root radiation. In this case the injury was twenty years old. Note the straightness in *A* and luxation of the third forward on the fourth. The patient was tracted by a bed halter for several days, with complete disappearance of symptoms. *B* shows the fusion of the third, fourth and fifth spinous processes. This patient was completely relieved from painful symptoms and has comfortable motion of the head and neck.

1. Hyperextension is as generally applied in the reduction of fractures of the spinal column as is straight line traction in the reduction of fractures in long bones.

2. The anterior longitudinal ligament when interpreted correctly acts as the main reducing medium as well as the main check strap opposed to excessive hyperextension.

3. Laminectomy as a decompressive procedure occupies a distinctly secondary place to that of hyperextension.

4. Determination of spinal subarachnoid block by the Queckenstedt test is an invaluable test before and after hyperextension and as a criterion for laminectomy.

5. Skeletal traction by means of the Crutchfield tongs is much superior to any other method of traction and when used properly is completely sufficient for the reduction of fractures, dislocations and fracture dislocations.

The following routine is observed in the emergency service:

1. Medical responsibility begins at the site of the accident. The ambulance personnel is instructed to place the head in immediate hyperextension with a blanket roll or other material under the neck, and an attendant remains in charge of the head position throughout all transport directly to the hospital bed, never once allowing the head to be bent forward or lifted as for a drink of water.

2. When the patient has been transferred to the hospital bed a halter is applied to take over the hyperextension. Five pounds of weight is attached through a pulley, and the head of the bed is elevated.

3. Not until the patient is so established in hyperextension with traction is the preliminary x-ray survey

permitted. A lateral film is then taken and an anteroposterior film particularly to show the odontoid. An anteroposterior film otherwise is mostly a deception.

4. Meanwhile a neurologic examination is made. If there is no evidence of spinal cord involvement and the preliminary films are negative, the case is further investigated in the roentgenologic department at leisure with bilateral oblique films, the odontoid films being repeated if necessary and films taken in the sitting position, positions 1 and 2, as heretofore mentioned.

Fig. 7—Outline of areas commonly involved in cervical spine lesions. From Tilney, Frederick, and Riley, H. A: *Form and Functions of the Central Nervous System*, ed. 2, figure 174, page 166, the somatic dermatomes (Dejerine), courtesy of Paul B. Hoeber, Inc., New York.

If the lateral projection in position 1 shows elimination of the normal forward curvature and all other evidence is negative, this in and of itself is sufficient to indicate the application of a hyperextension collar, to be worn without interruption for a minimum of three weeks, this period being the time of sound repair of

Fig. 8—Typical sixth nerve root radiation. Note narrowing between fifth and sixth cervical vertebrae, also exostoses of the posterior edges of the body. History is that of violent flexion ten years prior to advent of disabling symptoms. Is relieved by halter traction and by maintaining proper posture.

fibrous tissue. A great many cases of chronic disability involving both intervertebral disks and posterior spinal joints will thus be prevented.

OUTLINE OF DEFINITIVE TREATMENT

When the survey x-ray shows a gross lesion such as a crush fracture, unilateral or bilateral dislocation, fracture dislocation or fracture of the odontoid process:

1. Skeletal traction is almost invariably indicated.
2. If there are neurologic signs, skeletal traction also is indicated.
3. Provision should be made to raise or lower the pulley and weight traction and the amount changed to suit the case. Up to 45 pounds of weight has been used over a considerable period of time. However, 15 to 25 pounds with skeletal traction is ordinarily quite sufficient.
4. In cases of unilateral or bilateral dislocations or fracture dislocations, it is important to start traction

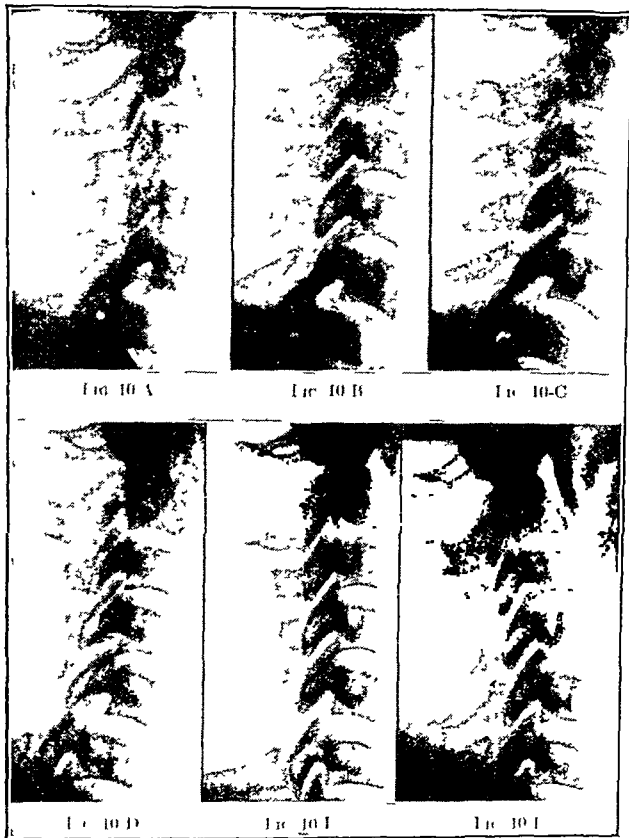

Fig. 9—Reduction with skeletal traction under roentgenographic control, reproduced from the *Journal of Bone and Joint Surgery* by courtesy of W. G. Turner. This method consists in gradual reduction by proper interpretation of the skeletal traction method. In cases of bilateral complete dislocations with or without subarachnoid block, skeletal traction is applied using 25 pounds pulling in line with the vertebra above the dislocation. Lateral films are taken at ten minute intervals, and it is found that after twenty minutes or more the processes are unlocked. At this time the head traction is lowered in order to induce hyperextension, thus replacing the jumped process. The traction is then reduced to 8 pounds or less. In the case cited the author states that the subarachnoid block was completely relieved. See footnote 13a.

in a straight line. Traction in flexion is dangerous because of avulsion of the posterior roots. Traction in extension is not effective because of the check strap effect of the anterior longitudinal ligament.¹² Straight line traction therefore under x-ray control, as much weight being used as is necessary to disengage the articular processes, is the rule. This procedure has been illustrated by Cone and Turner (fig. 9).¹³

12 Davis, A. G. Tensile Strength of the Anterior Longitudinal Ligament in Relation to the Treatment of 132 Crush Fractures of the Spine, *J. Bone & Joint Surg.* 20:429-438 (April) 1938.
13 Cone, W., and Turner, W. G. The Treatment of Fracture Dislocations of the Cervical Vertebrae by Skeletal Traction and Fusion, *J. Bone & Joint Surg.* 19:584-602 (July) 1947.

In the rare case in which dislocations are found irreducible by skeletal traction, one resorts to the Taylor¹⁴ or Walton¹⁵ technic. In spite of several attempts, some dislocations or fracture dislocations remain irreducible. Resort to operative approach such as that outlined by Rogers,¹⁶ is justifiable either for the removal of an obstructing articular process with fusion or simple fusion.

5. If there is nerve involvement or complete paralysis with a definite level, a Queckenstedt test should be made. Traction can be easily maintained and the position remain unchanged with such skeletal traction while the patient is turned on his side. If there is a complete block it is obviously important to attain complete restoration of the caliber of the spinal canal at the point of fracture or dislocation. Hyperextension, more than any other one factor, will bring this about. After a roentgenographic check has demonstrated full reduction or full hyperextension, another spinal tap is immediately done; if the block has been released, there is obviously no indication for laminectomy. If the pressure readings are still negative, laminectomy may be indicated. In spite of the well known futility of laminectomy in such cases, if laminectomy is to be done it should be done under local anesthesia and as quickly as possible. Allen¹⁷ has shown that spinal cord substance has the ability to recover from pressure up to five hours but that if pressure is continued longer the condition is irreversible.

When there is partial paralysis it is important to have repeated neurologic examinations at short intervals to determine progress or not of the lesion. In cases showing progressive paralysis or where the roentgenogram shows definitely the intraspinal projection of a bone fragment such as a fractured lamina, an emergency laminectomy is indicated. Clinical experience has shown that hyperextension is much more effective as a decompressor than is laminectomy. The projection of the posterior upper angle of the vertebral body into the spinal canal is the most frequent compressing medium. This deformation disappears with adequate hyperextension, releasing the block. Several cases showing an initial block have shown a restoration of pressure in the lumbar needle after hyperextension or manipulative reduction. Too often laminectomy proves to be an ante-mortem exploration and the cord is found pulvified. A number of fatal cases in which complete reduction had been attained by hyperextension in which laminectomy was not done because of its apparent futility have shown pulvified cords on necropsy. Prediction in any

13a. This method seems by far the safest and simplest of the manipulative procedures. It recognizes that pulling in a straight line is without danger because of the check strap effect of the anterior longitudinal ligament. It also recognizes that, once the facets are released, strong traction is contraindicated, so the traction is reduced to a negligible amount. It has been my practice that when such pure dislocations are properly reduced a plaster collar should be applied with the neck in hyperextension as soon as possible after the reduction has been accomplished. This is done in order to allow repair of the posterior ligaments in the short position, otherwise progressive luxation or recurrence of the dislocation may be experienced. There are numbers of cases on record in which this type of recurrence has been experienced. It is therefore important after the reduction has occurred not only to remove all traction but to immobilize the cervical spine in complete hyperextension in a rigid irremovable plaster collar for the necessary length of time for healing of the torn ligamentous tissues, which is from three to four weeks.

case is impossible when the case of complete paralysis is first seen because of the fact that edema, contusion, hemorrhage and compression may temporarily produce complete signs and it is quite impossible to differentiate these entities.

6. Fractures of the first and second cervical vertebrae with the exception of fractures of the odontoid defy classification as to treatment. Fractures in these vertebrae, however, obey the general rule as regards the immediate application of the Crutchfield tongs, although they are frequently an exception to the rule of hyperextension. Experience has taught that the head may have to be lowered or raised, depending on the appearance of the odontoid in the lateral projection. As soon as the odontoid has become stable and the fragments have been correctly apposed, this position should be maintained either by the tongs or by a plaster collar, which may be fitted while the tongs are still in place. It is important to eliminate all motions in rotation, nodding or lateral tilting for several months.

7. Fractures or defects of the accessory processes call for individualized treatment, depending on the part involved. Both Oppenheimer⁸ and Mensor¹⁸ call attention to such defects. Clay shovelers' fracture involving the spinous processes at the cervicodorsal junction also claim attention as a separate clinical entity.¹⁹ None of these have been encountered in this series.

CONVALESCENCE

Here a single general rule may be said to cover the entire conduct of convalescence to the point of sound healing. Hyperextension is that rule. Nowhere is it more necessary to maintain complete hyperextension throughout convalescence than in the cervical spine. Whether the patient is recumbent or ambulatory, whether the condition is a unilateral or a bilateral dislocation or a compression fracture, whether a partial luxation or a suspected intervertebral disk lesion, whether the patient must look skyward or not to hold the extension, the rule holds. Removable braces are the least trustworthy, irremovable plaster casts the most dependable. In fashioning such plaster collars or Minerva jackets, the principal criterion is the separation of the jaw from the chest. A number of cases appear in the literature in which redislocations have occurred after complete reduction because of inadequate splintage. Recent ligamentous lesions should be protected for three to six weeks, complete dislocations for three months, compression fractures for three months, odontoid process fractures for three to five months. Where fracture dislocations are found to be irreducible and there are no paralytic signs, posterior fusion of two or three of the vertebrae in the involved region is quite sufficient to produce a fully functioning spine minus symptoms except for slight limitation of mobility.

PROGNOSIS

In the 61 hospital admissions for serious accidents there were eleven deaths. Autopsies, which were obtained in most of the fatal cases, showed irreparable pulpefaction of the cord. In the remainder of the serious injuries full recovery has occurred for the most part. Several patients showing complete signs of paralysis on entering the hospital have recovered complete or

nearly complete function without laminectomy. In the 134 cases of all types there were complaints of arm or hand signs in 35. Several cases of wry neck were among the 73 ambulatory admissions.

In view of the rocker movement characteristic of the cervical vertebrae, it is illogical to separate lesions involving luxation of the posterior articulations from those of the disk. Injuries affecting the one inevitably involve the other, since the vertebra moves as a whole. The more severe the degree of luxation, the greater the probability of involvement of the disk. In several such cases there has been complete disappearance of painful symptoms following fusion. Judging from the mechanics of the injury, it would appear that, where a disk protrusion is definitely demonstrated, fusion of the involved area should accompany the disk operation or follow it. Otherwise the ligamentous laxity may continue to cause symptoms and indefinite pain radiation over the area for which the disk operation was done. Prognosis in such cases therefore depends on rules of practice yet to be elaborated in a field which has not yet been adequately exploited and in which much progress is at present being made.

CONCLUSIONS

1. Elimination of the normal forward convexity of the cervical spine indicates mechanical derangement of the posterior intervertebral joints.

2. Specific diagnoses are possible in many hitherto obscure cervical injuries when properly executed roentgenography and neurologic findings are correlated.

3. Present day roentgenologic, neurologic and orthopedic technic when combined permit a more favorable prognosis in all types of injuries except those with complete neurologic signs.

4. Further investigation and end result studies are necessary to differentiate fully the luxation type from the disk protrusion type of cervical injury and for the proper remedy for the combined lesion.

716 Sassafras Street.

ABSTRACT OF DISCUSSION

DR. JOHN DUNLOR, Pasadena, Calif.: A few years ago I visited Dr. Darrach's clinic, and Dr. Barbara Stimson tried to demonstrate to me what she was terming "unilateral dislocations" and which I had been calling "unilateral dislocations" for a great many years. In manipulating those cases, in some instances we were able to get definite proof that something happened with the reduction, and immediately the patient was relieved after recovering from the anesthesia. On the other hand there have been a great many cases in that group with manipulation in which nothing seemed to happen, and the patient was partially relieved but went around with a sore neck for a good many weeks afterward. I am wondering if Dr. Davis will tell us whether or not he believes that that group of cases is probably the sprained neck of which he speaks. A good many years ago I began to see ruptures of the spinous processes from about the seventh cervical down to the second dorsal, where the ligamentum nuchae had apparently pulled away the spinous processes. When I started to do that work it was almost impossible from an x-ray point of view to get pictures which would demonstrate these fractures. I should like Dr. Davis to go into more detail concerning the dislocations and the anterior dislocations which are not demonstrated in the facets.

DR. RALPH K. GHORMLEY, Rochester, Minn.: I am not sure how important these lesions are in the acute stage, but it certainly is true in my experience that many of the patients come to physicians later on—perhaps three, four or five years later—

18. Mensor, M. C.: Injuries to the Accessory Processes of the Spinal Vertebrae. *J. Bone & Joint Surg.* 19: 381-388 (April) 1937.

19. Hall, R. D. M.: Clay Shovelers' Fracture. *J. Bone & Joint Surg.* 22: 63-75 (Jan.) 1940.

with painful necks in which there is evidence of some trauma. If the trauma had been recognized at the time of occurrence, the condition might have been alleviated and subsequent disability prevented. One question I want to ask Dr. Davis is whether or not he believes in manipulation of dislocations of the cervical portion of the spinal column under anesthesia or whether he prefers traction methods.

DR. FRANK R. OBER, Boston: In an anteroposterior x-ray view of the cervical spine one may derive a good deal of help by drawing transverse lines across the centers of the vertebrae which extend for 2 or 3 inches beyond the center. If these lines are not parallel, one may conclude that some damage has been done to the cervical spine. All lateral x-rays of the cervical spine should be taken with the patient sitting as Dr. Davis recommends, head erect, head flexed and head extended. A study of these three views will give one a good idea of any disturbances of the physiologic curve in the cervical region. Furthermore, the sitting position allows the shoulders to drop so that one will get a view of the first dorsal as well as all the cervical spines. I do not believe it is always possible to correlate the x-ray appearance with neurologic symptoms of the peripheral nerves. For instance, writers' cramp can be due to spasm of the scalenus anticus group of muscles as well as from narrowing of the intervertebral foramina. The pain from cervical spine lesions is not always located in the arm and hand. Pain under the shoulder blade may be a characteristic symptom. One must remember, however, that one can get spasm of the scalenus anticus muscles in arthritis of the cervical spine as well as in cases of congenital shortening of that muscle or in the presence of cervical ribs.

DR. A. G. DAVIS, Erie, Pa.: Dr. Dunlop used the term "sprain." This paper attempts a more specific diagnosis than the word "sprain" implies. A sprain is either a torn muscle, fascia, ligament or joint capsule. Roentgenologists argue that spasm in the cervical region should produce more hyperextension than normal because the great mass of musculature is on the posterior aspect of the cervical spine. My contention is that the person is leaning away from the point of greatest tenderness, and the point of greatest tenderness is the particular posterior facet where the capsule is torn. The first structure to part must be the capsule surrounding the involved pair of facets. The next structure involved is the posterior longitudinal ligament. A large number of the indeterminate so-called "sprains" that we treated with physical therapy, "hantleg" stretching and so on seem amenable to more rational treatment. If we analyze cervical injuries on the basis of the "whiplash" mechanism, regardless of the nature of the accident, and realize that the momentum of the head continues on after the moment of impact or throw and that the extreme excursion is immediately followed by a recoil induced by the powerful posterior muscles, the element of deception so introduced makes less of the injury than it actually is. The question of involvement of the ligamentum nuchae is eliminated by the absence of hematoma, ecchymosis and swelling, these signs being absent. The answer to Dr. Ghormley's question is that, whether the reduction is gradual or by manipulation, general anesthesia is never used because of the hazard. May I draw your attention to the difference in approach of roentgenologists and orthopedists. To a roentgenologist "seeing" is "believing," and he is careful to commit himself no further than visual evidence indicates. The orthopedist must make allowance for the unseen. The fact of negative evidence in the lateral and anteroposterior projections does not disprove the presence of a luxation. The dense structure of one accessory process conceals lesions of another. Oblique and special positional radiography to some extent overcomes this concealment factor. Dr. Ober aptly mentions the scalenus syndrome. This entity must always be eliminated, especially in cases exhibiting pain radiation to the fingers and thumb. The scalenus syndrome, however, is not associated with a straight cervical spine, nor would one expect other evidence of pathologic change in the cervical spine. This seems a significant point of differentiation.

Clinical Notes, Suggestions and New Instruments

BICUSPID AORTIC VALVE WITH RUPTURE OF CUSP

MAJOR WILLIAM H. FLYTHE AND CAPTAIN JAMES C. WREN
MEDICAL CORPS, ARMY OF THE UNITED STATES

A white soldier aged 29 was admitted to the hospital complaining of excruciating substernal pain radiating to both arms. He had been well until approximately one hour before admission to the ward, when, while walking at a normal gait, he was suddenly seized with a viselike pain centered at the top of the sternum radiating down the sternum and into both arms. He experienced severe vertigo and almost collapsed. He was immediately nauseated and vomited several times. Moderate dyspnea and diaphoresis were present. In spite of these symptoms he was able to walk to the admitting office of the hospital, not more than 100 yards away, where he was seen by the officer of the day and admitted to the medical service.

The past history revealed nothing of significance. It should be noted that the patient had been an active athlete, having

Ventricular surface of aortic cusp with longitudinal tear.

pitched soft ball professionally and semiprofessionally during the past fifteen years. He was admitted to the hospital on two occasions in February 1943 for an upper respiratory infection, and on both occasions his cardiovascular system was described as normal on physical examination.

The family history was entirely negative.

On physical examination the temperature was 97 F., pulse rate 78 per minute and respiratory rate 22 per minute. The patient was obviously in acute distress. An ashen pallor was present and the extremities were cold and clammy. The pulse was Corrigan in type and the systolic blood pressure was 108 and the diastolic 44. The heart was not enlarged to percussion. On auscultation a loud harsh systolic murmur was heard over the entire precordium, being loudest over the upper end of the sternum. A long blowing diastolic murmur, loudest at the left third intercostal space, also was present. The lungs were clear, the liver was not enlarged and no peripheral edema was present.

Laboratory studies revealed a red blood cell count of 4,600,000, white blood cell count of 10,000 and a hemoglobin of 85 per cent. The Kahn reaction was negative. A sedimentation rate revealed a fall of 5 mm. in one hour. Urinalysis showed no abnormal findings other than a moderate number of granular casts. Blood culture showed no growth after forty-eight hours. A nonprotein nitrogen determination forty-eight hours after

admission was reported as 60 mg. per hundred cubic centimeters. A portable x-ray examination of the chest on the third hospital day showed apparent enlargement of the heart to the left. The aorta was widened in the ascending portion and in the arch. The lung fields were completely cloudy throughout with the exception of the extreme apexes, the appearance being typical of pronounced pulmonary edema.

A clinical diagnosis of ruptured aortic cusp was made on admission, the diagnosis being based on the sudden onset of severe substernal pain together with physical signs of a definite aortic insufficiency which had not been present on previous physical examinations in this hospital.

During the subsequent course of his illness large doses of morphine were required to control substernal distress, especially during the first twenty-four hours. The patient was put into an oxygen tent. Within eighteen hours after admission there was evidence of beginning congestive heart failure, i. e. increasing cough with blood tinged sputum, increasing dyspnea and cyanosis, steadily increasing pulse rate, and rales at both lung bases. By the second hospital day there was evidence of cardiac enlargement by physical examination and considerable increase in moisture in the lungs. Congestive heart failure progressed rapidly despite all the usual measures, including rapid digitalization, and the patient died sixty-two hours after admission.

The autopsy, which was performed by Capt. Joseph I. Mossberger, revealed much congestion throughout the lungs save at the apexes, where there was moderate congestion. Dissection of the pulmonary vessels revealed no evidence of embolism or thrombosis. The heart weighed 400 Gm. The coronary arteries were normal in size and showed no evidence of occlusion. Dissection of the coronary arteries showed numerous small atheromas in the walls. The pulmonic valves appeared normal. The cusps of the mitral valves were normal in length but were spotted with numerous small atheromas. The tricuspid valves appeared shortened. The aortic ring was apparently dilated and presented only two aortic cusps. The right cusp was decidedly enlarged, measuring 5 cm. between its upper attachments to the aorta. It had no nodulus and presented a longitudinal tear of the lamina of the ventricular surface. This tear exposed the raw surface of the lamina of the aortic surface for an area 2 cm. in length and 8 mm. in width. The tear is demonstrated in the accompanying illustrations. The valve was thickened, contained numerous cholesterol spaces and in one area showed slight calcification. The aorta presented a few atheromatous lesions in its wall just above the aortic cusps. The heart and microscopic sections were reviewed by Capt. Joseph H. Eisner. The pathologic diagnoses were as follows:

1. Bicuspid aortic valve.
2. Rupture of aortic cusp.
3. Atherosclerosis of the aorta with subintimal hemorrhage and recent thrombus formation.
4. Atherosclerosis of the aortic cusps.
5. Atheromatosis of the mitral valve and coronary arteries.
6. Subepicardial punctate hemorrhages and ecchymosis.

COMMENT

Pathologically the cause of the rupture was unusual. No evidence of syphilitic aortitis or of bacterial implant on the aortic valve was found, the rupture apparently occurring at the site of an atheromatous plaque. An interesting feature of the case clinically was the severity of the substernal pain, which during the first thirty-six hours was quite severe and was not entirely alleviated by frequent doses of morphine. The pain was characteristic of that produced by myocardial anoxemia. Although angina pectoris is not uncommon in the presence of aortic insufficiency, pain of this severity is not usually encountered even where the diastolic pressure is much lower. It seemed to us that the most likely explanation for the severity of the pain was the sudden increase in demand on the heart muscle produced by the rupture of the aortic cusp and the consequent aortic insufficiency, together with a decrease in coronary circulation following a lowered diastolic pressure.

A SIMPLIFIED SUCTION UNIT FOR INTESTINAL DECOMPRESSION

D. J. LEITHAUSER, M.D., DETROIT

The Wangensteen method for suctional drainage of the gastrointestinal tract is now widely used in the management of surgical patients. At first it was used for relief of intestinal obstruction, and more recently it has been employed to combat abdominal distention of all types, particularly after operation. In some instances it is used preoperatively as a prophylactic measure, particularly in cases in which distention may be anticipated.

The value of the procedure of gastrointestinal decompression is firmly established, but the Wangensteen apparatus presents certain difficulties that make the procedure burdensome, especially to the nursing staff. The equipment is cumbersome to handle, and its function is frequently interrupted by faulty connections, collapsed or kinked tubing and at times too much suction. Errors in setting it up may even cause reversal of flow, filling the gastrointestinal tract with water. I have found it particularly difficult to maintain suction with these units in patients subjected to early rising after operation, because of the necessity of disconnecting the apparatus frequently.

Suction unit for intestinal decompression.

To eliminate these difficulties, a simple siphon suction unit has been substituted; this functions equally well and avoids all the difficulties presented by cumbersome equipment and multiple connections. Since intra-abdominal pressure is always greater than atmospheric pressure, and since this is increased in proportion to the degree of distention or rigidity, actual suction is unnecessary. The simple T tube arrangement makes use of siphonage plus the elevated intra-abdominal pressure and functions as well as positive suction.

DESCRIPTION

A glass T tube connects the Levin or Miller-Abbott tube (A) to a rubber tube of a larger lumen (B), whose opposite end is immersed in a bottle below water level. The bottle is placed on the floor beside the bed. A short rubber tube is attached to the vertical arm of the T tube. The patency of the Levin or Miller-Abbott tube is determined by applying a clamp on B and then injecting and aspirating water with a large syringe through C. The clamp on B is then released and water is injected into the bottle on the floor, to prime the unit. A clamp then is placed on C, and the unit is ready to function. Gas passing through the tubing frequently breaks the siphon suction, but this is compensated by increased intra-abdominal pressure, which automatically reestablishes suction. Occasional flushing of the tubing to eliminate mucous plugs and priming are the only attentions needed to keep the apparatus functioning. Elimination of the aspirating bottle or bottles and substitution of the T tube connection does away with multiple connections

and stopper through which leaks may occur. If the lumen of the glass T tube is the same as that of the rubber tubing, leaks in the system are avoided and equal pressure is maintained throughout.

This simple unit has been used to provide decompression of the gastrointestinal tract in surgical cases for over a year. By the time it had been used six months other surgeons at St. Joseph Mercy Hospital had also adopted it, so that at present the older type of apparatus is seldom used. The nurses are enthusiastic about the simpler unit, because it is so much easier to regulate and keep functioning satisfactorily, and much more easy to set up and to handle.

14727 Jefferson Avenue, East.

ERGOTAMINE TARTRATE IN THE TREATMENT OF WAR NEUROSES

LIEUTENANT COLONEL ROY R. GRINKER
AND

MAJOR RUSSELL J. SPIVEY

ARMY AIR FORCES, MEDICAL CORPS, ARMY OF THE UNITED STATES

Since ergotamine tartrate has been recommended as a useful drug in the treatment of "battle reaction,"¹ it was thought that it might prove valuable in the treatment of "operational fatigue" (war neuroses) in flying personnel returned to this country from combat.

Patients selected for treatment with this drug, were those with evidence of sympathetic overactivity, manifested particularly by increased restlessness, tremor, sleeplessness, tension and agitation. The dosage given at first was that recommended by Heath and Powdermaker: 3 mg. for the first dose, then 2 mg. every three hours for ten days. Because of untoward symptoms this dose was quickly modified to 2 mg. every four hours for four doses daily for ten days. All patients in this report were given the latter dosage, except the first 3, who were given the larger dose for the first twenty-four hours only. All were confined to the ward during treatment and were carefully examined each day.

A total of 16 patients received the ergotamine tartrate (Gynergen, Sandoz); 1 mg. tablets were used. Thirteen of these developed toxic symptoms, notably pains in the legs and arms. Phlebitis developed in 3 patients; in 2 actual thrombi occurred. No improvement of the symptoms of sympathetic overactivity was observed in 10 patients. Only 2 showed improvement in their tremors while taking the drug but reverted to their previous status when it was discontinued. There were 2 others who showed improvement in both sleep and tremor, but 1 of these successes was due to abstinence from alcohol while under treatment. One stutterer showed improvement in his speech. Another slept better while under treatment but did not show any change in restlessness or tremor. None of the benefited patients maintained improvement after the drug was discontinued.

Two additional groups were given the same dosage of ergotamine tartrate. One group of 11 patients suffering with "operational fatigue" were selected at random. They were scattered about the hospital in the various wards and were not housed together. Eight of the 11 developed pain and soreness in the inner aspects of the upper third of their thighs after receiving an average total of 13.7 mg. of the drug. Of the 3 who developed no symptoms, 2 showed no change in blood pressure and 1 showed a lowered blood pressure. Of the 8 who developed symptoms, 2 manifested no significant blood pressure change and 6 showed a lowering of blood pressure.

Eleven normal healthy male adults were given the same dosage simultaneously with the patients. Eight of the 11 developed the typical pain and soreness in their thighs after an average total dose of 12 mg. Of the 3 who had no untoward effect, 2 showed no significant blood pressure change and 1 showed

an elevation. Of the 8 developing symptoms, 1 showed a slight elevation, 3 no change and 4 a lower blood pressure.

Experience with the first group of 16 patients led to the interpretation of the pain and soreness of the thighs as an untoward effect of the drug and as a precursor to potential vascular change. Since 3 of the original group of patients had developed a phlebitis following the complaint of pain and soreness, it was decided to stop medication on both of the later groups at the end of the third day, when each had received a total of 24 mg.

Ergotamine tartrate was originally used because of the properties as an orthosympathetic inhibitor by Heath and Powdermaker, who reported success in 20 cases. Goodman and Gilman² state that the autonomic blocking effect of ergotamine in man is slight and irregular. It however damages the vascular endothelium, producing vascular stasis, thrombosis and gangrene.

According to these statements there should be little reason to consider ergotamine tartrate valuable in the treatment of sympathetic overexcitation, and toxic effects could be anticipated. Moreover, rational therapy of war neuroses should be directed not against the symptoms but toward the basic causes. This is as axiomatic in psychiatry as in other fields of medicine. It is for this reason that "uncovering technics" are employed successfully.³

CONCLUSIONS

1. Ergotamine tartrate in tablet form, given 2 mg. four times daily to an average total dosage beyond 12 to 14 mg., produces symptoms which are interpreted as evidence of toxicity.
2. Improvement was infrequent and not sustained.
3. In our hands ergotamine tartrate is not useful in the treatment of "operational fatigue" as seen in this hospital.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports. HOWARD A. CARTER, Secretary.

ZENITH RADIONIC HEARING AID, MODEL B-3-A, ACCEPTABLE

Manufacturer: Zenith Radio Corporation, Chicago 39.

This is a vacuum tube instrument of three tubes consisting of a transmitter, a magnetic bone conduction receiver and a battery unit. Weights and overall dimensions of the various parts are as follows: transmitter, 5¼ by 2¾ by 1 inch; weight, 5 ounces; receiver, magnetic bone conduction, standard size. Batteries weigh 13 ounces. Total weight of the entire instrument is 20 ounces.

Batteries.—Voltages and current drains are as follows:

A battery, 1.5 volts. Current drain at full volume, 90 milliamperes.

B battery, 45 volts. Current drain at full volume, 1.2 milliamperes.

Acoustic Gain.—The Council tests were made on an observer with impaired hearing. There is no standard method for testing bone conduction.

Overall gain for speech, 35 decibels. The test was made in a free tone field at a distance of 5 feet from the loud speaker. The range of frequency response was tested with an electrical mastoid device measured by response on a cathode ray oscillograph. The frequency response included 4,000 cycles. However, there was considerable distortion in the wave at all frequencies, but this apparently did not influence speech intelligibility.

Physical and Mechanical Features.—The instrument differs in no way either in appearance, dimensions or weight from Zenith Model HA originally submitted to and accepted by the Council.

2. Goodman, L., and Gilman, A.: *The Pharmacological Basis of Therapeutics*. New York, Macmillan Company, 1941.

3. Grinker, R. R., and Spiegel, J. P.: *War Neuroses in North Africa. The Tunisian Campaign (January-May 1943)*. New York, Josiah Macy Jr. Foundation, September 1943.

From the AAF Convalescent Hospital (Don-Ce-Sar Place), St. Petersburg, Fla.

1. Heath, R. G., and Powdermaker, Florence: *The Use of Ergotamine Tartrate as a Remedy for "Battle Reaction,"* J. A. M. A. 125: 111-113 (May 13) 1944.

Performance.—This bone conduction instrument performs in a satisfactory manner and could certainly be used when such a combination is indicated. The construction and caliber of constituent parts all measure up to Council standards.

Recommendation.—The Council on Physical Medicine voted to include the Zenith Radionic Hearing Aid, Model B-3-A, in its list of accepted devices.

ZENITH RADIONIC HEARING AID (MODEL A-3-A WITH AIR CONDUCTION RECEIVER) ACCEPTABLE

Manufacturer: Zenith Radio Corporation, Chicago 39.

This is a vacuum tube instrument of three tubes consisting of a transmitter, a magnetic air conduction receiver and a battery unit. Weights and overall dimensions of the various parts are as follows:

Model A-3-A with magnetic AC receiver: transmitter, $5\frac{1}{4}$ by $2\frac{3}{4}$ by 1 inch; weight, 5 ounces; receiver, $\frac{7}{8}$ inch in diameter. Batteries weigh 13 ounces. Total weight of the entire instrument is 20 ounces.

Batteries.—Voltages and current drains are as follows:

A battery, 1.5 volts. Current drain at full volume, 90 milliamperes.

B battery, 45 volts. Current drain at full volume, 1.2 milliamperes.

Acoustic Gain.—The Council tests were made by trained observers using fitted ear molds in a tone field (sound proof room) seated 5 feet from the loud speaker delivering frequencies of pure sine wave characteristics. Tests for speech were made on an observer with impaired hearing.

Volume Control Set at	Tone Control at Position	Frequency						
		256	512	1,024	1,448	2,048	2,896	4,096
$\frac{1}{2}$	1	10	14	13	13	21	6	3
$\frac{1}{2}$	4	9	10	10	13	17	6	3
Full	1	14	24	28	30	25	15	10
Full	4	21	29	20	23	25	15	7

Overall gain for speech, 39 decibels.

Physical and Mechanical Features.—The instrument differs in no way either in appearance, dimensions or weight from Zenith Model HA originally submitted to and accepted by the Council with one exception: it has a new type neutral colored cord and air conduction receiver. Cord noise is much reduced, and the inconspicuousness of the receiver is an advantage. The earpieces are similar to those supplied with the original instrument.

In some cases it has been found that they do not give an adequate fit, under which conditions a molded earpiece is more satisfactory. The air conduction receiver for this unit is a bit different in characteristics from that used with the A-2-A. The phone is marked on the back with a letter B.

Performance.—The acoustic gain of this unit is somewhat greater than Model A-2-A. However, at maximum intensity there is a certain amount of overload and case noise. It is the opinion of the Council that it would be impossible to use the soft rubber tip earpiece supplied with this instrument if high intensities were required. Again the tone control, as in the other model, fails to give

a sharp frequency shift but gives rather a reduction of intensity. With tone control in number 1 position one gets the overall frequency response of the instrument. In number 2 position the low frequencies are attenuated. In number 3 position both highs and lows are attenuated. The number 4 steps up the lows.

Recommendation.—The construction and quality of parts are satisfactory. This together with the actual acoustic gain for both tones and speech qualifies the aid for acceptance by the Council. The Council on Physical Medicine voted to include the Zenith Radionic Hearing Aid, Model A-3-A, with air conduction receiver in its list of accepted devices.

Zenith Radionic Hearing Aid.

ZENITH RADIONIC HEARING AID, MODEL A-2-A, ACCEPTABLE

Manufacturer: Zenith Radio Corporation, Chicago 39.

This is a vacuum tube instrument of two tubes consisting of a transmitter, a magnetic receiver and a battery unit. Weights and overall dimensions of the various parts are as follows: transmitter, $5\frac{1}{4}$ by $2\frac{3}{4}$ by 1 inch; weight, 5 ounces; receiver, $\frac{7}{8}$ inch in diameter. Batteries weigh 13 ounces. Total weight of the entire instrument is 20 ounces.

Batteries.—Voltages and current drains are as follows:

A battery, 1.5 volts. Current drain at full volume, 90 milliamperes.

B battery, 45 volts. Current drain at full volume, 0.60 milliamperes.

Acoustic Gain.—The Council tests were made by trained observers using fitted ear molds in a tone field (sound proof room) seated 5 feet from the loud speaker delivering frequencies of pure sine wave characteristics. Tests for speech were made on an observer with impaired hearing.

Volume Control Set at	Tone Control at Position	Frequency						
		256	512	1,024	1,448	2,048	2,896	4,096
$\frac{1}{2}$	1	9	12	12	15	14	15	10
$\frac{1}{2}$	4	10	10	10	10	10	12	7
Full	1	19	20	20	27	27	18	10
Full	4	23	26	15	25	25	16	10

Overall gain for speech, 35 decibels.

Physical and Mechanical Features.—The instrument differs in no way either in appearance, dimensions or weight from Zenith Model HA originally submitted to the Council except that it has a new type neutral colored cord and air conduction receiver. This is an improved feature. Cord noise is much reduced, and the inconspicuousness of the receiver is an advantage. The change in type of vacuum tube which the maker reports does not change the performance of the instrument to an appreciable extent. The earpieces supplied are similar to those supplied with the original instrument. In some cases it has been found that they do not give an adequate fit, under which conditions a molded earpiece is more satisfactory.

Performance.—The acoustic gain for pure tones and speech is adequate. The tone control still does not give a straightforward shift in frequency but rather a modification of intensity. With tone control in number 1 position one gets the overall frequency response of the instrument. In number 2 position the low frequencies are attenuated. In number 3 position both highs and lows are attenuated. The number 4 position steps up the lows.

Recommendation.—The construction of the instrument meets all requirements of the Council, and the individual parts are all of good quality. The performance of the instrument is entirely adequate for use by a person with impaired hearing. The Council on Physical Medicine voted to accept Zenith hearing aid Model A-2-A for inclusion in its list of accepted devices.

Council on Foods and Nutrition

ACCEPTED FOODS

The following additional foods have been accepted as conforming to the Rules of the Council on Foods and Nutrition of the American Medical Association for admission to Accepted Foods.

GEORGE K. ANDERSON, M.D., Secretary.

FOODS FOR SPECIAL DIETETIC PURPOSES (See Accepted Foods, 1939, p. 295).

SATURDAY, JANUARY 20, 1945

PHILADELPHIA SESSION CANCELED

The Board of Trustees of the American Medical Association, after consideration of all factors involved, has officially announced the cancellation of the Ninety-Fifth Annual Session of the Association scheduled for Philadelphia June 18-22. This is the fourth time in the Association's history and the second time during the present war that an annual session has not been held. In 1861 the annual session was postponed for a year because of the outbreak of the war between the states. In 1862 it was again postponed for a year. The 1943 annual session scheduled to have been held in San Francisco was canceled. Last year the session was held in Chicago. It is expected that a meeting of the House of Delegates will probably be held in 1945 in Chicago at a time to be announced later in THE JOURNAL. The action this year is taken voluntarily in order to cooperate to the fullest possible extent with the request of the Office of Defense Transportation and in the interest of the nation's war effort.

BREAD ENRICHMENT SHOULD BE CONTINUED

Among the important applications of the numerous advances in nutrition is the development of the program for enrichment of food. By order of the War Food Administration all baker's white bread, white rolls and sweet rolls must be enriched with vitamins of the B complex and iron to stated levels. The content of enriched baked goods in thiamine, niacin and iron is thus brought to the desirable high levels of these constituents found in similar products made from whole wheat flour. The value required for riboflavin slightly exceeds that of whole wheat preparations.

The continuance of these benefits to the nation's nutritional standard is not now assured beyond the

duration of the emergency. The compulsory enrichment of baker's white bread and rolls terminates with the resolution of the wartime powers of the War Food Administration. The problem then reverts to the individual states as to whether enrichment of these foods will continue to be required. Legislation at the federal level would affect only those products handled in interstate commerce. Both federal and state action will be required to insure entirely effective regulations for enrichment of food throughout the country.

The need in the American diet for the additional amounts of nutrients supplied by enrichment of baked goods has been shown by dietary surveys. A summary of these surveys published by the National Research Council¹ revealed a strikingly high proportion of the diets below the recommended levels in one or more essentials. A detailed study of the average American diet prior to the advent of enriched flour and bread showed the thiamine content to be 0.8 mg. per 2,500 calories,² whereas the National Research Council's recommended daily allowance for thiamine is 1.6 mg. for this caloric intake. In an extension of the work mentioned the daily intake of riboflavin was determined to be 1.4 mg. and that of niacin 11 mg. per 2,500 calories.³ Both these figures are below the value of 2.2 and 15 mg. respectively recommended by the Research Council for these dietary essentials.

The enrichment of flour and bread is considered particularly desirable because these foods are consumed daily in significant amounts by practically every one. They are relatively cheap foods and are therefore used extensively by the low income groups whose diets are most in need of improvement. The addition of thiamine, riboflavin, niacin and iron to white flour and bread serves to replace what has been lost in the milling process. The appearance and taste of the original food are not changed; the consumer receives added nutritional value without change in food habits or conscious effort. Enriched white bread is not intended to supplant the use of whole wheat bread by those preferring the latter.

The effect of the widespread increase in consumption of these enriching substances on the nation's nutrition as a result of mandatory enrichment of all white bread and rolls is difficult to measure accurately at this time. All methods of appraisal, however, indicate a definitely beneficial influence. It has been calculated⁴ that, if all the flour and white bread in the average prewar diet should be enriched, the average thiamine intake would be increased to 1.6 mg., that of riboflavin to 1.6 mg.

4. The Facts About Enrichment of Bread and Flour, prepared by the Committee on Cereals, Food and Nutrition Board, National Research Council, September 1944.

and that of niacin to 17 mg. per 2,500 calories.³ This would enable the average diet in this country to meet the recommended allowances for thiamine and niacin, with something to spare. The amount of riboflavin still falls short of the recommended level, but new information indicates that the daily allowance for riboflavin may appropriately be lowered. As more direct evidence of the contribution of bread enrichment to the improvement of this country's nutritional status, the statement made by Dr. Jolliffe of the New York University College of Medicine at a public hearing held by the War Food Administration Jan. 21, 1943 is particularly significant:

I attribute to bread enrichment a marked and unmistakable decrease in florid beriberi and florid pellagra in my wards at Bellevue Hospital. In 1938-39 little bread was enriched; in 1942-43 seventy five per cent or more has been enriched in New York City. This has been accompanied by a decrease of three fourths in our cases of florid beriberi and two thirds in florid pellagra.

The benefits which accrue to the vastly greater number of individuals suffering from milder chronic degrees of these deficiency states, in many cases unrecognized or attributed to other causes, can probably be considered the greatest contribution of enrichment. An improvement in the general health and well being and an increased efficiency in the population as a whole may be anticipated, since carefully controlled experimental groups have shown measurable benefits as a result of dietary increases of enrichment materials to enrichment levels.

The Food and Nutrition Board of the National Research Council and the Council on Foods and Nutrition of the American Medical Association, groups particularly cognizant of the beneficial effect of nationwide enrichment of white bread on the American dietary, have called attention to the necessity of making this requirement permanent throughout the country. In 1941 the Board of Trustees of the American Medical Association approved the recommendations for bread enrichment. The American Public Health Association has recently adopted a resolution favoring appropriate federal and state action for the perpetuation of the benefits of enrichment. South Carolina, Louisiana, Alabama, Texas, Mississippi and Kentucky have already adopted legislation requiring the enrichment of all white bread and white flour sold within their borders. Similar legislation is being given consideration at present in other states. The physician, who can give effective support to these measures, should recognize the contribution made by the enrichment of bread to the improvement of our diets. If the nutritional gains thus far made are to be maintained, the active interest of every informed person who has the public interest at heart will be required.

PROLONGING THE ACTION OF PENICILLIN

The versatility of American medical research is well illustrated by the announcement of a third successful method of prolonging the therapeutic action of penicillin. Trumper and Hutter¹ of the National Naval Medical Center, Bethesda, Md., are credited with this technic.

Earlier investigators² found that within an hour after intravenous injection of penicillin fully 60 per cent of the injected dose is excreted in the urine. The penicillin titer of the blood stream falls to zero before the end of the second hour. As a result of the evanescent character of this drug, many of the earlier clinical cases failed of cure. In the Bethesda Hospital, of 10 patients with gonorrhea given a single intramuscular injection of 50,000 Oxford units of penicillin only 2 were cured. Two doses of 50,000 units each given at six hour intervals effected a cure in only 55 per cent of the cases.

The first successful method of prolonging the action of penicillin was by excretory blockade. This was effected by the simultaneous intramuscular injection of diodrast³ or of p-aminohippuric acid.⁴ Both of these substances reduce the rate of renal excretion of penicillin by about two thirds. As a result of this reduced excretion the penicillin titer of the blood stream is maintained at a therapeutic level for nearly six hours, well beyond the two hour effective therapeutic period in control, nonblockade, patients.

The second successful method of accomplishing the same result was by suspending penicillin in some inert oil that would slow down the rate of absorption from locally injected tissues. Romansky and his associates⁵ tested several oils and waxes for this purpose and found that a mixture of peanut oil and from 1 to 6 per cent of beeswax gave the best results. Intramuscular injection of 50,000 Oxford units in 2 to 2.5 cc. of beeswax-peanut oil so slows down the rate of absorption from the injected muscle as to maintain an effective therapeutic level in the blood stream for a period of from six to seven hours. The mixture was tested on 65 patients with gonorrheal urethritis, 64 of whom were cured by a single intramuscular injection. This represents a 98 per cent therapeutic success as contrasted with the 20 per cent success in their earlier treatments with the same number of penicillin units dissolved in saline solution.

A third successful method is currently reported from the Bethesda Medical Center.¹ This is based on an attempt to delay absorption by prolonged vasoconstriction.

tion in the injected muscle. Vasoconstriction was effected by a chilling technic. An ice bag was applied to the deltoid region two hours before the intramuscular injection and replaced for a period of six to twelve hours after the injection. With this technic a single intramuscular injection of 50,000 units of penicillin in saline solution maintains an adequate bacteriostatic level of penicillin in the blood stream for from six to twelve hours. Thus far the chilling technic has been applied to 18 gonorrheal patients, 17 of whom were cured by a single intramuscular injection. This is a percentage of cure equal to that with the penicillin-beeswax-peanut oil mixture. Application of an ice bag two hours in advance of the injection renders the injection painless.

The chilling technic may be applied in research with other therapeutic agents. With specific antisera it might well reduce allergic reactions.

Current Comment

FEDERAL HOSPITAL CONSTRUCTION PROGRAM

An appropriation of \$110,000,000 is suggested in a bill pending in Congress to assist states in the construction of hospitals and related facilities. The bill, S. 191, was introduced January 10 by Senator Hill of Alabama for himself and Senator Burton of Ohio. It was referred to the Senate Committee on Education and Labor, of which Senator Murray of Montana is chairman. Of the total federal appropriation suggested, \$5,000,000 will be available to assist states to inventory existing hospitals, to survey the need and to develop a program for new construction. An additional \$5,000,000 will be available to cover the administrative expenses in carrying out state plans. The remainder will be used, if the legislation is enacted in its present form, for construction purposes. On a federal level the program will be under the direction and supervision of the Surgeon General of the U. S. Public Health Service aided by a federal advisory council all members of which, except one, will be appointed by the administrator of the Federal Security Agency. The Surgeon General will serve as chairman ex officio of the council. On a local level a state agency must be designated in plans submitted for approval as the administrative agency. The term "hospital" is broadly defined. It will include "public health centers and general, tuberculosis, mental, chronic disease, and other types of hospitals, and related facilities, such as laboratories, outpatient departments, nurses' home and training facilities, and central service facilities operated in connection with hospitals, but shall not include any hospital furnishing primarily domiciliary care." The term "public health center" is defined to mean "a publicly owned facility for the provision of public health services and medical care, including related facilities such as laboratories, clinics

and administrative offices in connection with public health centers." It must be assumed that the Senate Committee on Education and Labor, through its recently created permanent subcommittee, which, it is announced, will consider all proposed public health legislation, will desire to give careful consideration to this legislation before recommending its enactment. A detailed analysis of the provisions of the bill will appear in an early issue of THE JOURNAL.

MORE STUDY OF FOREIGN LANGUAGES NEEDED

This war has apparently not been accompanied by any significant outbursts against the music, language or literature of enemy countries such as occurred in World War I. Indeed, the study of German, Japanese and some other languages has been actually stimulated, though this has been principally a practical project, wholly associated with contemplated military operations or ultimate occupancy of foreign countries. After the war scientific and medical discoveries will doubtless be made in what are now enemy countries and will be described in their own language and scientific periodicals. The opportunities and facilities for the study of foreign languages are far greater in this country than they have ever been in Australia, whose medical journal has recently taken editorial¹ notice of the need for such study there. The linguistic ability of most Americans compares unfavorably with that of Europeans and others who are exposed early in life to two or more languages. Many leaders of educational opinion in this country have claimed that there is no good reason to teach foreign languages in the schools before the usual high school age. This claim should be reexamined. Medical science has never failed to recognize the need for widespread dissemination of new discoveries; a most important instrument is comprehension of the language in which the discovery is made. Any improvement in methods, therefore, by which a greater knowledge of foreign languages can be achieved in this country will deserve the support of the medical profession.

CONGRESSES ON MEDICAL EDUCATION AND INDUSTRIAL HEALTH

At the time of going to press the status of the Congress on Medical Education and Licensure, which is scheduled to convene February 12-13, and of the Congress on Industrial Health, scheduled for February 13-15, is not altogether clear. Since these two meetings were organized for the purpose of contributing to the war effort the Office of Defense Transportation has been asked for a ruling on whether these meetings should be held. As soon as a decision has been reached the profession will be promptly notified through the pages of THE JOURNAL. In the meantime, participants and prospective visitors to the congresses should plan on their being held.

MEDICINE AND THE WAR

ARMY

FLIGHT NURSE SAVES LIFE OF PATIENT INJURED IN CRASH LANDING

The War Department recently revealed the heroic action by a flight nurse aboard an Air Transport Command evacuation plane in the South Pacific. Second Lieut. Mary Louise Hawkins, Redwood City, Calif., was the flight nurse in charge of 24 litter patients, Palau battle casualties, en route to Guadalcanal when the plane began running short of gasoline. The pilot, passing over a tiny island, noted a clearing 150 feet square fringed by tall coconut palms and decided to attempt a crash landing in this restricted area rather than ditch the plane at sea. During the landing of the C-47 a propeller tore a hole in the side of the fuselage; patients and crew were uninjured with one exception. The injured man received a severe cut in his throat, which severed the trachea but missed the jugular vein. Through the swift and efficient work of Lieutenant Hawkins the man's life was saved. She devised a suction tube from various accessories including an asepto syringe, colonic tube and the inflation tubes from a Mae West. With this contrivance she was able to keep the man's throat clear of blood until aid arrived nineteen hours later. Lieutenant Hawkins graduated from the Highland Hospital School of Nursing, Oakland, Calif., in 1942 and immediately enlisted in the Army Nurse Corps. After a year at AAF Hospital, Walla Walla, Wash., and Camp Kearns, Utah, she was chosen for special training as a flight nurse. Assigned to the Air Transport Command in August 1944, she was sent immediately to her present station in the South Pacific Wing.

COLONEL ANTHONY J. LANZA RETIRES

Col. Anthony J. Lanza, director of the Occupational Health Division, Preventive Medicine Service, Office of the Surgeon General, has retired from active duty to resume his work as assistant medical director of the Metropolitan Life Insurance Company. Dr. Lanza is credited with the establishment of the Army Industrial Hygiene Laboratory at Baltimore, which makes surveys and recommendations for the control of occupational hazards on request by any army branch. He was also instrumental in organizing the Armored Medical Research Laboratory at Fort Knox, Kentucky, to conduct medical, physiologic and engineering research for the Office of the Surgeon General so that our fighting men might be better equipped and prepared to withstand the rigors of adverse climatic conditions. Prior to entering the Army Dr. Lanza was for sixteen years assistant medical director of the Metropolitan Life Insurance Company in charge of industrial hygiene. He is also a member of the Council on Industrial Health of the American Medical Association.

HOSPITALIZATION OF RETURNING CASUALTIES

Major Gen. Norman T. Kirk, Surgeon General of the Army, recently stated that the large increase in casualties returning from the battlefronts is making it impossible to send all patients to hospitals near their homes. General Kirk said that more than 30,000 sick and wounded were brought back to this country in December—an increase of 300 per cent over July. The three principal factors which guide the medical department in the selection of the hospital to which a soldier is sent are:

1. Where can the patient get the best treatment for his particular case?
2. What hospitals offering such specialized services have the facilities to care for additional cases?
3. What suitable and available hospital is located nearest to the soldier's home?

ARMY AWARDS AND COMMENDATIONS

Captain Samuel S. Pasachoff

The Bronze Star Medal was recently awarded to Capt. Samuel S. Pasachoff, formerly of New York City. The citation read "For meritorious service in connection with military operations against the enemy as general surgeon, 45th Evacuation Hospital, Semimobile, from Nov. 24, 1943 to Aug. 1, 1944 in England and France. Captain Pasachoff performed skilful operations on wounded soldiers, often going for long periods without rest or relief. In addition he designed and constructed numerous surgical articles which proved highly essential to the efficient operation of the hospital. The professional skill, ingenuity and devotion to duty displayed by Captain Pasachoff reflect credit on himself and the military service." Dr. Pasachoff graduated from New York University College of Medicine in 1929 and entered the service March 22, 1943.

Major Harvey D. Bingham

Major Harvey D. Bingham, formerly of Mercer Island, Wash., was recently awarded the Bronze Star Medal "for meritorious service in connection with military operations against the enemy from June 26 to Aug. 1, 1944. As chief of the surgical service in a station hospital at Kwajalein, Major Bingham organized a surgical staff which functioned smoothly in spite of crowded facilities and inadequate equipment. Established as a 400 bed unit, the hospital cared for 2,900 casualties in less than six weeks. Major Bingham's surgical skill and judgment were a vital factor in the excellent professional care rendered." Dr. Bingham graduated from Washington University School of Medicine, St. Louis, in 1938 and entered the service Feb. 3, 1941.

Major J. Marion Kirtley

Award of the Bronze Star was recently made to Major J. Marion Kirtley, formerly of Crawfordsville, Ind., who is now commander of the medical detachment of the 22d United States Infantry with the 3d Army in Germany. His detachment turned in a remarkable performance in caring for the wounded in the Hurtgen forest fighting recently in Germany. Dr. Kirtley graduated from Indiana University School of Medicine, Indianapolis, in 1936 and entered the service Dec. 14, 1940.

Captain Garland N. Adamson

Capt. Garland N. Adamson, surgeon of a tank battalion and formerly of Chicago, was recently awarded the Bronze Star Medal "for heroic achievement in connection with military operations against an enemy of the United States in France, on Nov. 11, 1944. . . ." Dr. Adamson graduated from Meharry Medical College, Nashville, in 1922 and entered the service in November 1942.

Major Edmund G. Beacham

The Bronze Star Medal was recently awarded to Major Edmund G. Beacham, formerly of Baltimore, for "meritorious achievement in military operations against the enemy from June 7 to July 4, 1944, in Normandy, France." Dr. Beacham graduated from the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, in 1940 and entered the service Feb. 3, 1941.

Major Anthony S. Terranova

Major Anthony S. Terranova, formerly of Brooklyn, was recently awarded the Bronze Star Medal for "meritorious achievement." Dr. Terranova graduated from Georgetown University School of Medicine, Washington, in 1937 and entered the service July 15, 1942.

NAVY

CAPTAIN RODDIS HEADS MEDICAL
HISTORY BOARD

Vice Admiral Ross T. McIntire, chief of the Bureau of Medicine and Surgery, has recently approved establishment of a Medical History Board in the Bureau of Medicine and Surgery which will be headed by Capt. Louis H. Roddis (MC), U.S.N., as chairman.

"The board, through its chairman, shall report to, advise and assist the Surgeon General on all matters within its scope as hereinafter defined.

"The functions of the Medical History Board shall be (a) to plan, cause to be prepared and edit an official history of the Medical Department of the U. S. Navy, (b) to coordinate historical activities within the Bureau of Medicine and Surgery and the Medical Department, as well as with the Office of Naval History, Navy Department, and (c) to maintain liaison with such other military and civilian historical agencies as may be required in the prosecution of the functions of this board.

"Establishment of said board does not preclude Medical Department personnel or activities preparing historical accounts on subjects of special cognizance, concern or interest, but any and all of these must be submitted to said board for review, coordination and approval before they can be recommended for official publication."

MEDICAL CORPSMAN WINS NAVY CROSS

The Navy Cross for "gallantry and intrepidity in action" while attending wounded and dying men on the Normandy beaches on D day, has been awarded to August B. McKee, hospital apprentice, formerly of Jersey City. The citation, in part, states that "McKee, cut off from the remainder of his unit and working under intense enemy fire with utter disregard for his own safety, attended the wounded with such skill and devotion to duty as unquestionably to have resulted in the saving of many lives. . . . Working with such meager supplies as he was able to salvage from the dead and wounded, and all the while working under intense machine gun and sniper fire, McKee attended the wounded and comforted the dying with utter disregard for his own safety until help reached him several hours later."

LIEUTENANT ROBERT BROWNE MISSING

Lieut. Robert Browne, formerly of Peoria, Ill., has been reported missing in action. He was stationed on a destroyer which was lost in the Philippine action in October. Dr. Brown graduated from the University of Illinois College of Medicine, Chicago, in 1942 and entered the service in July 1943.

MISCELLANEOUS

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

Induction Center, Grand Central Palace, New York: Diagnosis of Anorectal Disease, Dr. Max Cowett, February 2; Head Injuries, Dr. Eli Jefferson Browder, February 9 and February 16.

U. S. Naval Hospital, Philadelphia: Edema and Dehydration, Dr. F. William Sunderman, February 9; The Esophagus and Its Diseases, Dr. L. H. Clerf, February 23.

U. S. Naval Hospital, Naval Operating Base, Norfolk, Va.: Nucleus Pulposus—Medical Aspect, Dr. Lay Martin, February 2; Nucleus Pulposus—Surgical Aspect, Dr. Francis J. O'Tenasek, February 2.

Newton D. Baker General Hospital, Martinsburg, W. Va.: Indications for Use of Sulfonamides and Penicillin, Dr. Henry B. Mulholland, February 5; The Psychoneuroses in War, Dr. David C. Wilson, February 5; Treatment of Patients with Paraplegia Due to War Injuries, Dr. Donald Munro, February 19; Liver Diseases Seen in the Present War, Dr. Wallace Yater, February 19.

Station Hospital, Fort Belvoir, Va.: Skin Eruptions of the Eczema Group, Dr. Walter O. Teichmann, February 26.

Station Hospital, Fort George G. Meade, Maryland: Evaluation of the Surgical Risk, Dr. John Finney Jr., February 2.

Crile General Hospital, Cleveland: Technique of Closure of Colostomies, Dr. Thomas E. Jones, February 27.

Air Base Hospital, Patterson Field, Dayton, Ohio: Diagnosis and Surgical Treatment of Acute Cholecystitis, Dr. George Heuer, February 21.

Winter General Hospital, Topeka, Kan.: Plastic and Maxillary Surgery, Dr. Earl C. Padgett, February 22; Clinical Psychiatry, Dr. G. Leonard Harrington, February 22.

Tilton General Hospital, Fort Dix, New Jersey: Pathology of Allergy, Dr. Paul Klemperer, January 22; Post-Traumatic Pain Mechanisms, Dr. E. A. Rovenstine, January 29.

Mayo General Hospital, Galesburg, Ill.: Dermatologic Diseases, Drs. James H. Mitchell and Francis E. Seneat, January 24.

Birmingham General Hospital, Van Nuys, Calif.: Classification and Diagnosis of the Anemias, Dr. Alvin Foord, January 24.

U. S. Naval Hospital, Oceanside, Calif.: Psychosomatic Medicine, Dr. Douglas Eaton, January 25.

U. S. Naval Hospital, Corona, Calif.: Surgery of the Traumatic Abdomen, Dr. Charles Phillips and Comdr. Gaylord Bates, January 25.

FILM DEPICTS FITTING PROSTHESES

British Information Services (30 Rockefeller Plaza, New York 20) now has available, for sale or loan, a two reel film revealing the part played by modern science in the making and fitting of artificial limbs, by means of which disabled persons are able to follow their old occupations or work at new trades which are taught them at government training centers. Participating in the film are former patients of Roehampton, one of Britain's hospitals devoted to the treatment of limbless war casualties. The film shows how men with the new artificial limbs are able to work at engineering, drafting, carpentry and other highly skilled occupations which formerly they could not have followed. With the aid of special tools provided by the government they are now able to work at these trades with speed and absolute efficiency. Some of these men are shown in their hours of recreation playing tennis, golf, billiards or table tennis or at work in the garden.

HOSPITALS NEEDING INTERNS
AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment service:

(Continuation of list in THE JOURNAL January 13, page 97)

MASSACHUSETTS

Boston City Hospital, Boston. Capacity, 2,537; admissions, 35,559. Dr. James W. Manary, Medical Director (resident—dermatology-syphilology).

Cambridge Hospital, Cambridge. Capacity, 272; admissions, 6,078.

Dr. F. A. Washburn, Director (intern, July 1; male preferred).

Burbank Hospital, Fitchburg. Capacity, 270; admissions, 4,303.

Mr. Richard Bullock, Directing Trustee (intern, April 15, July 1).

Waltham Hospital, Waltham. Capacity, 215; admissions, 3,299.

Mr. Walter R. Amesbury, Administrator (2 interns, July 1).

RHODE ISLAND

Homeopathic Hospital, Providence. Capacity, 196; admissions, 5,439.

Mr. Carl A. Lindblad, Director (interns, July 1).

WEST VIRGINIA

Charleston General Hospital, Charleston. Capacity, 380; admissions, 10,439.

Dr. John E. Cannady, Director (intern; resident—pathology).

WISCONSIN

Luther Hospital, Eau Claire. Capacity, 176; admissions, 4,006.

Mr. N. E. Hanshus, Manager (intern, March 1; intern, May 1;

general resident, July 1).

ORGANIZATION SECTION

ANNUAL CONFERENCE OF SECRETARIES AND EDITORS OF CONSTITUENT STATE MEDICAL ASSO- CIATIONS

SECOND SESSION, FRIDAY AFTERNOON

DR. D. L. CANNON, Montgomery, Ala., Presiding

(Continued from page 106)

Medical Service Plans

DR. ROBERT E. S. YOUNG, Columbus, Ohio: The wealthy, who comprise perhaps 6 to 8 per cent of our population, need no particular plan for medical care. There is a large group of the middle and low income levels that definitely need a plan for prepayment medical insurance. The C. I. O. in its report on hospitalization in 1940 pointed out that nine out of ten of its families are dependent on the wage earnings of one person, and that one third to one half of the poverty arising in each family is due to the illness of this wage earner. The people in this group desire insurance coverage. A great part of our population have already availed themselves of prepayment insurance. There are now approximately 15,000,000 people covered by the Blue Cross Hospitalization Plan. There are now approximately 18,000,000 subscribers covered by industrial and commercial insurance plans. Considering the number of people who are covered by labor plans, by benevolent associations and by brotherhood plans of various types, including their dependents as well, at least half of the population would seem to be already covered by some type of prepayment insurance plan.

There is a third group in our population, the indigent and the medically indigent, who need medical service and cannot and will not be able to pay for it. Prepayment insurance cannot reach this group. One might think that governments would be interested in protecting this group; apparently they are not. The indigent are receiving care from the medical profession and from the hospitals largely on a charity basis. Why isn't the solution of the problem simple? It is not simple because medical needs vary with different localities. The cost of medical care that is purchased on a need basis is higher in our Northern states and in our large cities than it is in the Southern rural areas. It would be difficult to fit a plan to all areas of the United States. Plans of this sort are pregnant with political power, and political power is interfering with the formation of a plan.

We have long known the cash indemnity plans which commercial insurance companies offer. We owe it to our county societies to educate them about the difference between a cash indemnity plan and a service plan. Few know the dangers and evils of both and the good points of both. In a cash indemnity plan it is fundamental that there is no contract between the physician and the patient. The contract is between the patient and the insurance company. This tends to fix the minimum fees for physicians, but it is no ceiling on maximum. This is important. A physician in times of inflated prices, as today, may charge more than an insurance policy will pay. He can receive payment from the patient, from the insurance benefit and an additional fee from his patient himself. In more normal times the fee probably would cover the service. In periods of depression it is doubtful if any physician would charge less than the minimum fee. This fixes the minimum fee for medical service. A service plan fixes the maximum fee. A plan such as the Michigan Medical Service, for example, started out as a pure service corporation. The fee schedule was a little lower than normal because physicians thought that if they collected all of their fees they would not suffer the loss usually taken in poor collections. However, these plans are nonprofit corporations. If premiums are adequate to cover the submitted bills and are building up, so that a reserve fund is being formed, either benefits must be increased ultimately or premiums must be lowered. If, however, the premiums collected are not suffi-

cient to cover the benefits or the medical bills, the medical bills must be prorated. Now in most service plans proration has been experienced. In other words, no floor is put under medical fees. They may go down as far as proration makes it necessary, but a ceiling has been placed on medical fees in that the physician cannot charge more than the fee schedule.

The Michigan Medical Service Plan found, as most service companies have found, that it was necessary to modify the pure service corporation and approximate a cash indemnity form. It therefore dropped out the medical service and kept only the surgical benefits. It agreed that, if a patient had an income greater than the income level set in the plan, the physician might charge an additional fee. In February 1943 the average income of people in the state of Michigan was \$52.81. These are Department of Labor statistics. The income level under the Michigan Medical Service Plan is \$2,500 for the family. This put virtually every one in the state of Michigan over the income level of the Michigan Medical Service Plan. It is necessary for the doctor to prove that an individual's income is higher than the income levels of the plan. This makes it difficult in these times for physicians to charge more than the fee schedule.

The second great danger in a service corporation that does not exist in a cash indemnity corporation is the intervention of a third party. I am using Michigan Medical Service because it is the largest service corporation. In the cities of Flint and Pontiac the physicians became dissatisfied with the plan and published a statement in the newspapers that they were going to drop out of it. There is considerable danger in service plans that are developed on a cooperative basis that a third party may take over the plan. In periods of depression people who have put off medical services because they were busy, perhaps working overtime, may delay their need for services until a more advantageous time. In a recession more service will be required under a service plan than is required now. If that becomes necessary, proration will probably again be necessary. The plan is dependent on pay roll deduction. If we have general unemployment the plan will cease to function. One of the men from the Michigan Medical Service, when I was there in 1942, stated that the Educational Research Department of Social Security had suggested that they underwrite the loss of the Michigan Medical Service, which I believe at that time was about \$700,000, if they would bring physicians under salaries, that being a fit cause for the expenditure of educational funds. I wonder what will happen to service plans if unemployment becomes general and unions insist on the operation of such plans. Have we opened ourselves to a subtle infiltration of federalization? I am afraid that we have and we at least should think about this point and build our defenses for it.

Blue Cross Hospitalization has long felt the need for an extension of its policy to cover medical, surgical and obstetric charges. In Ohio we found that Blue Cross first had attempted to form a stock company which it could control, but this plan had been rejected by the superintendent of insurance, who stated that it would be impossible for them to transfer funds from the Blue Cross for the purpose of starting another company. It then approached the Ohio State Medical Association with a plan for the development of a mutual insurance company which might be largely financed by physicians, with the thought and suggestion that this would give physicians control. It even stated that the board of trustees could be completely formed of physicians. However, in a mutual insurance company the incorporators have no power other than to appoint the board of trustees and the director. The money, funded and placed with the superintendent of insurance, has no power of control. The control in a mutual insurance company lies with the subscriber. It was thought by the directors of the Blue Cross movement that if proxies were sent down to the subscribers through a subscribers' committee—and a subscribers' committee had been organized by the Blue Cross director in Ohio to func-

tion in industry—they would be signed and returned to the director and he could then return the company. However, this is questionable. It has been my experience in studying plans all over the United States that labor is interested in control, and if proxies came down through their own subscribers' committees the proxies would be returned to the unions; then the unions would control the new mutual insurance company which was working with Blue Cross. If this should be true, the plan would then become a consumer cooperative. Because of the necessity that Blue Cross faced in its need for a policy to write these additional benefits, they could exert considerable influence on Blue Cross to conform to the consumer cooperative. Physicians then could be approached if they charged more than the cash indemnity benefit. The director of Blue Cross, who would also be director of the Mutual Insurance Company, could approach the hospitals and exercise some disciplinary power on physicians through the hospitals to maintain the fee schedule set up by the mutual insurance company. If that should be true—and we felt that it probably would be—the fee schedule would become only secondary in importance because it could be changed. For that reason in Ohio we rejected this plan of a mutual insurance company and suggested that a stock company be formed which would be controlled by the medical profession and would write medical, surgical and obstetric benefits on a cash indemnity basis. This new company will not be associated directly with the Ohio State Medical Association. If it should fail or if it should become unpopular, the Ohio State Medical Association would suffer. We hope that we may distribute the stock to a large number of physicians, that one physician may never own more than a small part of the stock, and that it will never pay dividends but that premiums and benefits will be adjusted, so that in effect it will become a nonprofit organization. The directors of Blue Cross in Ohio rejected this plan, since they saw nothing in it that they could carry to their board of trustees. We think that in their rejection we proved our point that they were not interested in a new company to cover the needs of the people but were more interested in control.

What do we need to further prepayment insurance? We need more people in our county societies who understand the principle of insurance. They must at least understand the differences between cash indemnity and service plans. We need county societies that are willing to discuss such problems. I think that we should start in the medical schools, and I suggest that chairs be established in medical schools to teach medical economics and sociology. We should include our medical students in our county societies under some type of membership and let them become interested in organized medicine. Our interest in organized medicine needs to be stimulated now. Any means that we can devise to stimulate it is necessary.

DISCUSSION

DR. WILFRID HAUGHEY, Battle Creek, Mich.: We have a medical service plan in Michigan; I participated in the development of it, from the time it started in our county medical society until the time it was adopted by the state; I am still on the board of directors; in fact, I am vice president. We had plenty of trouble; we were the originators; we had to do something for which there was no program; we were developing something new and we had to try and plan. We set up our plan first to cover complete medical and surgical care in the home, in the office and in the hospital, and we got stung. We had surveys made. We spent a lot of money trying to find out what it cost to take care of the people. We found out what the cost is in Michigan to take care of the people when they are paying their own medical service. We spent around \$20,000 to find that out. Then we took those figures and doubled them, figuring that we would have an adequate rate. If we had multiplied them by $4\frac{1}{2}$ we would have had an adequate rate. We started out with about 8,000 policyholders in the complete medical care program, and before we could finish them up at the end of the year we were in debt \$150,000. Now, we also started out with a surgical plan, which we are still running. We never were \$700,000 in the hole, but we were \$504,000 in the hole on Oct. 30, 1942. At that time we had prorated for four months. Instead of paying our doctors 100 cents on the dollar, we paid them 80 cents on the dollar. That

was part of the plan. Every cent of that has been paid back. We owe nothing. We have a little balance, a surplus or a reserve, whatever you would call it. We also have some funds to work on which we did not have to start with. We now have over 720,000 persons being served by the Michigan Medical Service. We have about \$300,000 of government bonds and quite a little money in the bank. We have some reserves set up for bills that the doctors haven't sent in yet. That was in the \$500,000. We are expecting to get those bills in and to pay them. Some of the Genesee County men did sign up with us at first. One man from Genesee County opposed the whole plan from the first. A lot from Genesee County have opposed it ever since. They said that we had no business to go into the insurance business anyway, that it was an insurance business and not a medical business. They wanted us to make a cash indemnity plan. The C. I. O. had some influence in our getting the Chrysler Corporation. They made a study of all insurance plans, nonprofit and profit, voluntary and everything else that they could find. They made a study that extended over four or five months. They published a pamphlet of sixty-odd pages, and the conclusion was that the best plan for their own interest was the Michigan Medical Service. While this company wanted to take out insurance in an old line company, they compelled them to take the Michigan Medical Service. That is where the C. I. O. helped us. C. I. O. did have a quarrel with some of the doctors up in Flint too, but the doctors in Flint did not come back after two months. They are not back yet. The doctors in Flint are practicing, not as cooperating doctors but as doctors who render service and send their bills. They still do not send their bills to the Michigan Medical Service. They send their bills to the patients. The patients send the bills to the Michigan Medical Service. The checks are written and accepted. There is one member of the C. I. O. on our board and I have seen him attend just two meetings in the last five years; none of those have been within the last two years. He attended one meeting when we were having trouble with the Genesee County delegation. He brought with him a whole committee, and the committee told us that they would see to it that Genesee County came into line. All they wanted was for the Michigan Medical Service to go ahead and do business. Within the next two or three years we are going to know whether we are going to be practicing medicine as individuals or as employees of the state. You should offer a service that will prevent the Murray-Wagner-Dingell bill. How are you going to offer a service unless you offer it through medical service plans, and how better to offer it than through a plan that is absolutely administered by the medical profession? There is no dictation.

DR. W. F. DONALDSON, Pittsburgh: No hospitalization dictation, Doctor?

DR. HAUGHEY: No, sir, we run our own plan.

DR. DONALDSON: Could you take time to outline your relations with Blue Cross?

DR. HAUGHEY: When we started, the Blue Cross plan had been working in Michigan. It had a sales organization and was a going concern, I think with around 150,000 subscribers. We hooked up with them. They sell our program at the same time they sell their own. They present both wherever they make presentations. Sometimes our program is taken and sometimes it isn't, as testified to by the fact that we have 720,000 certificates and they have 1,200,000. They got to the point this last spring where they could not sell more policies because the Michigan Medical Service had held up on our sales to big companies. We held up because of the deficit, which was never \$700,000, but we wished to pay it off. It is paid off. Now we are again selling policies, and we have sold over 100,000 policies in the last five months. Michigan Hospital Service has sold more than that. They sell our policy. They collect the money from the employer. It comes to the central office in one check for both hospital service and medical service. They pay us our part and we pay them a certain percentage for handling that part of our program. We are paying them 7 per cent right now for handling that part of the program, the sales and the collection from the employers and a lot of records and things that are kept, bookkeeping and so on. The rest of it

we handle ourselves, and our rate of cost is around 10 cents. We must sell these things. I think that Ohio is delaying Michigan by not coming into this. I think that any state that does not start something of this nature to meet the Wagner-Murray-Dingell bill is setting back the progress of our fight against regimentation of medicine. I do not see any other way to beat it than to offer what these dreamers are offering. Who is going to take this service? The working man does not stop to think things out. He takes what he is given. The government says "We will give you complete medical care, hospitalization, office and everything else." He accepts it unless we can show him something that is just as good and does not cost him as much. There is an item too! It does not cost as much under our plan as it does under the government plan. Kaiser was touted as having a wonderful plan. The Kaiser plan does not meet the services that Michigan is rendering to the doctors. It costs more and they don't give the services. The Kaiser plan charges \$50 extra for an obstetric case. The Kaiser plan charges \$10 extra for a tonsil case under 16 years of age. The Kaiser plan provides one hospital to which they can go. It provides a complete choice of doctors, provided the doctor is one in this hospital or on a certain list that is published in their circular. We make no restriction on the doctors. The patients choose their own doctors, and the doctors are getting their checks within about ten days or maybe two weeks.

DR. OLIN WEST, Chicago: Dr. Haughey, will you be good enough to explain the nature and extent of the service that is rendered under the Michigan service plan and to say whether or not it is contemplated that the total medical service feature will be reinstated?

DR. HAUGHEY: The Michigan Medical Service now renders surgical service in the hospital. It pays up to \$15 for x-ray service in connection with any surgical service or if it is contemplated. It pays for obstetric service in the hospitals. We have set up a tentative rate and authorized the sale of up to \$50,000 of those policies, and we expect to service them until we know some of the things that we have found out in surgery. When we find that our rates are right we expect to cover that. We are also studying complete service. We do not expect to offer it immediately, but we can. We think we know what it would cost, and we could offer it if the occasion demanded it. There is a lot of agitation in Michigan, and it comes chiefly from Genesee County, that we authorize surgical service any place but not in the hospital. They say that our paying for surgical service in the hospital clutters up the hospitals and they say that they cannot get their legitimate cases in because they have minor cases in the hospitals. Our experience with complete medical service is still ranking a little, we do not know the answer, nor does anybody else.

DR. WEST: Your contemplated medical service will be for hospitalized service only?

DR. HAUGHEY: That will all be service in the hospital.

DR. WEST: Your present volume does not include any medical service other than these surgical and obstetric cases?

DR. HAUGHEY: Surgical and obstetric is the present volume. We canceled out all of that other. In order to get on our feet we had to do so.

DR. H. H. SHOULDERS, Nashville, Tenn.: Doctor, may I ask if you have tried to sell it to individuals or just to groups?

DR. HAUGHEY: We sell it just to groups.

DR. SHOULDERS: You have had no experience with what the cost of the sale would be if it was sold to individuals?

DR. HAUGHEY: We will take a group as small as ten if it is a legitimate group.

DR. SHOULDERS: That is under one employer?

DR. HAUGHEY: One employer, a legitimate group, and that group must be 100 per cent. For the big groups we require 75 per cent coverage. We did not at first. We were told that 40 per cent coverage was perfectly legitimate and safe, but it is not. We found that out.

DR. R. L. SENSENICH, South Bend, Ind.: Does the 10 cent cost that you quoted include the 7 cent cost of acquisition?

DR. HAUGHEY: No.

DR. SENSENICH: That is a total of 17 cents?

DR. HAUGHEY: That makes a total of 17 cents. I am not sure of that. That 7 cents may be included in the 10 cents. I haven't looked that item up.

DR. SENSENICH: I should imagine that it would be more than 10 cents, based on other charges.

DR. HAUGHEY: I think the 10 cents covers our office and the 7 cents covers the other.

DR. R. B. ANDERSON, Fort Worth, Texas: I just wanted to ask if the obstetrics is covered only in the hospital.

DR. HAUGHEY: Obstetrics is covered only in the hospital. All of our service is covered in the hospital. The time that these laboring people suffer a catastrophe is when they have to go to the hospital. The average can take care of the cost of \$2 or \$3 for a visit at his home or at the office.

DR. F. F. BORZELL, Philadelphia: May I ask what experience you have had in your relationship with the Blue Cross plan, that is, in their selling the plan and turning the funds over to you? I am assuming that you adjudicate all claims, both of the subscriber and of the doctor.

DR. HAUGHEY: We do all that ourselves.

DR. BORZELL: Has the Blue Cross had any difficulties from that score, in that it is your agent and representative and then later on any questionable claims for medical service must be referred to the Medical Service Plan?

DR. HAUGHEY: The Medical Service takes the medical claim; the Blue Cross takes the hospital claim; then we have a committee that meets periodically and adjusts whatever differences there are.

DR. SHOULDERS: What is your present rate, Doctor?

DR. HAUGHEY: I think it is a basic 60 cents per month for an employed male. The employed female has to pay more.

DR. E. L. HENDERSON, Louisville, Ky.: Don't you include the family?

DR. HAUGHEY: We have a rate for the family too. The rate as assessed when we sell the policy is a schedule apportioned between the number of men and the number of women employed in the group that is insured, so that the rate is different for each factory.

DR. WINGATE M. JOHNSON, Winston-Salem, N. C.: North Carolina was the first state in the Union to have a hospital coverage. In 1935 Dr. Mannerzan was the president of the state medical society. He offered that as a recommendation. He was made chairman of the committee, which went to work, and we have had a Blue Cross plan in operation since 1936. A year ago last May we added to it the surgical and obstetric coverage.

DR. W. EDWIN BIRD, Wilmington, Del.: The Delaware plan was operating in the fall of 1935.

DR. GEORGE H. KRESS, San Francisco: You may be interested in knowing something about the statewide medical service on the service basis, that of the California Physicians Service, now in its sixth year, which has a gross income of \$1,500,000 on the unit basis, paid to the doctor for an office visit. The unit of payment is \$2.50. We are now paying \$2.25 and there is every prospect in the near future of the full normal unit being paid to our men. I am in full accord with what Dr. Haughey has said about the value of the service plan. I concur in his point of view, and I think most Californians would likewise, that the indemnity plan will only lead to disaster. You will not be able to sell it to the people and to the political powers when it comes to taking over, in case the government does ultimately take over. During the last year we found that it was desirable to make some changes in our mode of operation from our idealism of six years ago. The California Physicians Service started out with something like 5,000 professional members. It charged \$5 registration, which netted \$25,000. The California Society lent \$42,000. They made blunders and as time went on, just as Michigan had its experience of running into the red, so did California Physicians Service run into the red. This last year, instead of letting the California Physicians Service be an absolutely separate entity, we brought it back into the California Medical Association. To that extent I must oppose the recommenda-

tion of Dr. Young not to let the state society have anything to do with it. The most potent force from the standpoint of protection of the medical interests is your constituent state association and the component county societies. The indirect board of directors was a group of administrative members, voted in by the doctors, presumably from the congressional districts, but in a state as large as California it is not possible to bring them together. It was the board of administrative members that elected the seven trustees. We changed the setup through legislative action in our incorporation. Now the house of delegates of the California Medical Association recesses at its annual session and becomes the board of administrative members of the California Physicians Service.

DR. HAUGHEY: That is the way we do in Michigan.

DR. KRESS: And it is the board of administrative members that elects the trustees. The whole thing today comes back into the full and absolute control of the California Medical Association. It isn't the lay public that endangers a plan such as the Medical Service Plan. When you get to operating in your own groups and territories you will find that your troubles are within the profession itself. Just as Michigan has had troubles, so have we had troubles. In San Diego everybody is satisfied and the profession is working hand in hand with us. In Alameda there is a strong group that is reluctant to accept the program, as is Genesee County. By and large the members are working with us and are beginning to see the benefit of this setup. Before you start your plans, study carefully the Michigan and California plans, the service setups, because through trial and error, with no actuarial experience, they have learned some things. It would be a great pity for you to make the same mistakes that they made and had to learn at a loss of dollars and a great deal of trial and tribulation.

MRS. ELIZABETH D. BOLLIS, Honolulu, Hawaii: We have a medical plan in Honolulu that has now been operating since 1939. It was revised rather in 1939, and since its revision it has been most successful. It is, of course, much smaller than the Michigan and the California plans, but we give a medical service, a surgical service and a hospital service. We had no Blue Cross in Honolulu and so we had to start from scratch. All the doctors in the county participate. The doctors are paid for the service, and since the reorganization of the plan they have received 100 per cent of the bills that they have presented. The bills are presented according to a fee schedule. We had to start with the revision of the plan by taking the plans that were already in operation or, in most cases, proposed, and we took from them what we thought were the best provisions. Michigan has just told you of the experiences that it has had and so has California. Both California and Michigan must have a wealth of material in their statistics and in their experiences that these other plans that are just beginning to originate could profit by. In most plans the waiting periods are alike. In some plans the premiums are alike. You will have to meet your local conditions and your local doctors' wishes.

DR. C. A. SMITH, Seattle: I should like to say something about the Medical Service Bureau that exists in Washington, because it differs in some respects from that of any other state. Chronologically this practice was first established in Washington. It is between twenty-five and thirty years ago that the Pierce County Medical Society in Tacoma set up its Medical Service Bureau. Since that time five counties have set up these bureaus. Each one is autonomous, but the principles are the same in all of them. They furnish medical, surgical and hospital service to their clients. Something over a year ago the insurance commissioner of the state declared that these bureaus were in reality carrying on an insurance business and demanded that they be incorporated as insurance companies. After due deliberation the Washington Medical Insurance Corporation was established and the fifteen medical bureaus of the different societies carry on the business. According to the insurance corporation they provide service to individuals, to groups and to families. They provide medical, surgical and hospital services. Washington has never had anything to do with the Blue Cross. The medical service bureaus were established and working a good many years before it appeared. The men of

Washington could not see that the Blue Cross offered anything to employees that weren't already being furnished by the Medical Service Bureaus. Washington is one of the few states in which the Blue Cross is not working a plan. They sell their policies in Washington, but they work them through the Blue Cross headquarters in Portland, Ore., and have nothing to do with the medical bureaus' services. King County, which is the largest county, now has its own hospital and, strange to say, it has been presented to the bureau by the United States government. Two years ago, when the shortage of hospitals existed in all parts of the country, there was a shortage of beds in Seattle. Industry has been much expanded in Seattle by the shipbuilding yards. There was a great shortage of hospitals. PWA offered to allocate \$600,000 if the county commissioners would provide \$200,000 to build a 200 bed addition to the county hospital. Before the commissioners could do that they had to get the consent of the voters. When it was put up two years ago there was not a sufficient vote to carry that through, so then some of the officers of the King County Medical Service Bureau suggested that they should make an approach to accept this offer from the PWA. They investigated, and we all thought it was a great tribute to the success of the bureau and a mark of confidence by the government officials in their executive ability that they accepted the plan. About a month ago this Doctors' Hospital was completed and is now accepting patients. The cost was approximately \$1,000,000, of which the government supplied \$665,000 and the Medical Service Bureau, through its corporate body, which is called the Medical Service Corporation, provided the remaining funds. The local bureau averages about 80 patients continually in the hospital. They had a lot of trouble with the hospital previously as to financial arrangements, so that the remaining beds are open to the patients of any member of the King County Medical Society. The doctors in the state of Washington believe that the medical service bureaus established in the state are going to be a strong argument to oppose the establishment of state medicine. At every session of the legislature bills are introduced to carry out some kind of a state medical service. Probably in the coming session bills will be introduced as usual, but the setup of the medical service bureaus by the doctors will be a strong argument to be presented against it.

DR. YOUNG: I did not expect the men representing the service plans to be happy about my talk on the Michigan Medical Service. Do you still have the C. I. O. Grievance Committee in the Michigan Medical Service office?

DR. HAUGHEY: Yes, they do the work of men whom we had to hire otherwise to do it. They solve the problems out in the factories, and we had to have employees in the hospital do that. The Grievance Committee now does it better than we could do it.

DR. YOUNG: Is it true that, when the physicians in Flint and Pontiac published their newspaper article and dropped out, the C. I. O. passed a resolution counteracting that move?

DR. HAUGHEY: I don't know, but they took action counteracting it. I don't know about their passing a resolution. I know that the Flint doctors published things in the newspapers and they did a lot of those things, but the Flint doctors are still objecting to us, but they are taking our checks and they are doing the work.

DR. YOUNG: Did the C. I. O. use the Michigan Medical Service as a means of trying to unionize Ford?

DR. HAUGHEY: No. We had the Ford Company and we started out with around forty some thousand policies and built the number up to around seventy-two thousand policies in the Ford Company. We had an understanding with the Ford Company that they would renew when the year was up, but they sent auditors around to our office—the C. I. O. wasn't in there—this was the Ford Company that sent auditors around to our office to find out if we were making anything off of those Ford people. Well, we were, so they demanded one month's free service. We did not want to give it. The state insurance commissioner recommended that we give it because we were nonprofit. So we authorized the one month's free service. After that was authorized, Ford canceled and never came back.

DR. YOUNG: In theory a service organization is one that gives all of the medical service that the public is able to consume. I think it is a fundamentally wrong idea. It is the same as though we were to organize an insurance company which would make it possible for you to have an automobile as often as you want it. If we were to do that you would want one at least once a week because you would rather have a new one than have the old one washed. Your wife would have one that would match the color of every one of her dresses. The premium for such a plan would go up to the point where it would be impossible for you to keep it up. Now that is the fundamental principle behind a service organization. It is one that will give all of the medical service necessary. When any one starts a plan of that sort he gets into trouble. The Michigan Service did. The plan in San Diego that folded up last year did. The California Physicians Service did. When they get into trouble they modify their plan to the point where it approaches a cash indemnity plan. In Michigan they have said that their plan when it takes in people over a \$2,500 limit becomes a cash indemnity plan in that the physician can charge more. Some plans attempt to limit the services so that they put brakes on their service corporation, but when you start with a service plan you always keep the evils of the service plan. If we hit a recession, pay roll deductions will stop at least in part. People will have less work to do and it will be an opportune time to get things done that they have been putting off and the Michigan Medical Service may again run in the red.

DR. HAUGHEY: No, we will not.

DR. YOUNG: This opens up the possibility. You collect a number of premiums during the month and you do a number of medical services during the month. You pay for the medical service according to a fee schedule. If you pay according to a fee schedule, it depends entirely on the number of services that are rendered in a month. If a large number of services are rendered you may find that you are unable to pay them all and that you must prorate. If you find that the number of services is small, you will have to pay fewer bills and you will build up a surplus. If you build up a surplus—and I understand that you have a surplus—some one is going to ask how about reducing premiums or increasing benefits because it is incorporated as a nonprofit organization and should not build up too much of a surplus. When you do that then you have pushed it down to the point where any fluctuation in the value of the dollar or any fluctuation in employment jeopardizes the plan. What happens if we have inflation? Your physicians may be stuck with a fee schedule that is too low. I think the plan is based primarily on an economic system where employment is stable and the value of the dollar is stable. Most serious is the fact that it is so definitely associated with the state association. If the plan fails it will justify the charge that is always made that physicians are not competent to take care of financial matters and that we should turn the administration of all of this over to a lay group. If the plan were not associated directly with the medical association and it failed, it would be of no particular consequence to any one except those involved in it. Michigan has done a lot toward meeting the needs of the public and stopping socialized medicine. I wonder if in the long run they might not be making it possible for the government to finance their failure and then take it over by that method. I think this is a very difficult thing to foresee and that there are still some loopholes in the Michigan Medical Service Plan.

DR. HAUGHEY: We shall not fold up when we have a depression. Those people have to keep on paying their service charges, their monthly instalments, and those fellows will all promptly go on to the unemployment compensation rolls, and in order to be on the unemployment compensation rolls they must not be in the hospital. They must be ready to work, so they cannot come for any more surgical benefits if they are on unemployment compensation, which they all go on as soon as they get laid off. Our insurance commissioner has approved our building up a reserve sufficient to carry us about five or six months, and most of these unemployment conditions do not last that long. We believe that we are safe.

(To be continued)

MEETING OF THE CALIFORNIA MEDICAL ASSOCIATION

*Foreword and Resolutions Adopted by the House of
Delegates of the California Medical Association in
Special Session in Los Angeles on January 4, 5 and 6*

To the House of Delegates of the California Medical Association:

Your Resolutions Committee submitted a preliminary report at yesterday's meeting (Jan. 5, 1945) and it will be assumed that the members of the House have in mind the general tenor of that report. At yesterday afternoon's session twenty resolutions were presented, in addition to those previously submitted, and all these your committee had to consider between last evening's hour of adjournment and this morning's meeting, which was scheduled to begin at 9 o'clock. Your Resolutions Committee remained in session until after 1 o'clock this morning, and it now submits to you this supplemental report.

Before proceeding with consideration of specific resolutions, we believe it advisable briefly to review the immediate circumstances leading up to this special meeting of the House of Delegates of the California Medical Association, so that the house may bear in mind one fundamental point, which is that the house must give a specific answer to a specific question.

Early in December 1944 His Excellency Governor Earl Warren conferred with the officers and councilors of the California Medical Association and stated to them in substance that he favored and urged the establishment by law of a system for the distribution of the costs of medical care, to be financed, if necessary, through new and additional pay roll taxes. Governor Warren stated that he had an open mind as to the details of any such system. He requested the California Medical Association to inform him of the type of tax financed medical care plan, if any, that the association would approve.

Subsequently, officers and members of the association have held informal conferences with representatives of organized labor and a representative of the California farm bureau. Representatives of labor and a representative of the farm bureau have appeared before the council and before the delegates at this special meeting of the House of Delegates. The governor of the state of California has asked of us a question. We must now proceed to answer it.

Most of the resolutions submitted by members of the house and considered by the committee contain various answers to the governor's inquiry. Your committee felt that to consider each resolution separately would involve both duplication and unnecessary prolongation of this special three day session. Therefore your committee has prepared a substitute resolution containing a specific answer to the question that has been propounded to the association. The resolution proposes a plan for state assistance in the solution of the problem of the distribution of the costs of medical care, but it does not contain any acceptance, direct or indirect, of the basic provisions of any known compulsory health insurance system.

Your committee recommends that this house of delegates express its appreciation of the sincerity of purpose of the governor and the representatives of labor and of agriculture in their proposals looking toward a solution of the problems before us. We recognize with gratification that an important forward step has been taken in the furtherance of mutual understanding and cooperation between the California Medical Association and the leaders of the public its members serve. It is our earnest desire to seek the continued advice and cooperation of all parties having interests in the solution of our mutual problems.

Your committee now submits the following resolution:

Resolved, That the California Medical Association is of the firm conviction that no fundamental and revolutionary change in the practice of medicine should be made under present wartime conditions. If disruption occurs in the rendering of medical service, the result can well be a catastrophe for the people of the state. That major disruption would occur if health insurance were made compulsory by the state is self evident, regardless of approval or disapproval by the doctors of a new system in principle. This is true for two reasons: The doctors remaining in civilian practice after over 3,000, or approximately one third, have gone into military service are barely able now to provide medical service for a greatly expanded population and greatly expanded industry and they do

it by working to or beyond the limit of sustained endurance. If, now, they are forced to go through a period of change to a new and unfamiliar system of practice, medical service to the people will break down. This is not theory. We know from experience with California Physicians' Service that the process of educating doctors and patients, to say nothing of administrators, to operate under an unfamiliar system is not accomplished overnight.

Furthermore, from experience of California Physicians' Service, in the war housing projects where a full coverage plan was in operation it was found that the demand for service was vastly increased under a complete prepayment system—in fact as much as doubled. Without arguing how much increased service is or is not desirable, the plain fact is that the doctors are doing all they can now, and a large increase in demand for service will with absolute certainty break down medical care in California, and be it further

Resolved, That the California Medical Association cannot endorse any system of compulsory health insurance which has thus far come to its attention; and be it further

Resolved, That the California Medical Association is equally convinced that there is an existing problem with respect to the distribution of the costs of health services, and therefore its position with respect to such problems must continue to be a positive and progressive one, and be it further

Resolved, That as such a positive and progressive step toward the ultimate solution of the problem, the House of Delegates of the California Medical Association hereby proposes the following program, which it believes to be both desirable and feasible under all existing circumstances:

(a) An increase in the benefits of the California Unemployment Insurance Act, without increasing payroll taxes, to provide cash indemnities to wage earners when ill or injured through nonindustrial causes. Such cash indemnities would be primarily used for the payment in whole or in part of incurred hospitalization costs. This proposal is feasible because the present California unemployment benefits and the estimated cost of adding cash indemnities can well be financed within the existing unemployment tax structure.

(b) The California Medical Association is wholeheartedly in favor of the principle of distribution of the costs of medical care by means of prepayment, and its sincerity in this regard is evidenced by its expenditure of no inconsiderable money and effort for the development of California Physicians' Service and that California Physicians' Service has been offering to the public a statewide, nonprofit prepayment plan for the past five and a half years.

The California Medical Association respectfully insists that it is not an informed statement to characterize California Physicians' Service as a "failure because it covers only about 125,000 people." A brief review of its enrolment experience presents a fairer picture of its present status and future prospects. After its administrative organization was ready to operate in 1939, it took three weeks to enroll the first ten members. Rate of enrolment in its first four years averaged about 1,000 per month. Now, with its more advanced "seasoning," with improvement in compensation to doctors, with better public knowledge of and confidence in it, rate of enrolment of new members has risen to approximately 12,000 per month in the last four months of 1944. If it is fair to judge the future by past experience, California Physicians' Service is, just at this time, entering on a period of very rapidly increasing expansion.

The California Medical Association respectfully insists that, instead of characterizing California Physicians' Service as a failure because it covers as yet an insufficient number of people, the state government, management, labor and agriculture should implement and assist California Physicians' Service to attain its objectives.

Such assistance could well be a reduction of the employees' portion of the California unemployment tax for those employees who have joined California Physicians' Service or any other equivalent service. To illustrate this proposal. Under it, an employee enrolling in California Physicians' Service (or in one of the Blue Cross plans) would have a smaller sum deducted from his pay check each month than he would if he failed to join. The amount of this reduction would be small, but its smallness is not important because the existence of any incentive will unquestionably act as a tremendous aid to the growth of voluntary nonprofit plans. It may be claimed that this cannot be done without increasing existing taxes. Therefore the following information is of importance. The present California unemployment tax consists of 37 per cent of all payrolls, 27 per cent paid by the employer, 1 per cent paid by the employee. This tax fund is collected under the present law for the sole purpose of paying cash benefits to people unemployed through loss of work. Since the inception of the California unemployment system, the benefits paid out have been less than one third of the amount of the taxes collected. Even in previous years the benefits paid out averaged not over half the taxes collected. Therefore it is apparent that a tax reduction to encourage medical coverage can be added to the Unemployment Act without jeopardizing the solvency of the fund and without adding to the tax burden. California is in an advantageous position in this regard because it is one of the few states that impose a 1 per cent unemployment tax on employees in addition to the 27 per cent employers' tax. It is this 1 per cent which has resulted in the California fund becoming extremely large and further results in the feasibility of our suggested plan. For instance, the present surplus is \$621,708,167.89.

(c) A more rigid enforcement by the state of the various existing disease preventive measures and other public health laws should be undertaken. By this means, already at the command of the state, great strides can be made toward the reduction of the incidence of illness and disease. It must not be forgotten that all reductions in the incidence of illness decrease the cost of medical care. Better enforcement of existing preventive measures relating to tuberculosis, contagious diseases and, specifically, venereal diseases would reduce the incidence of these diseases and illustrate this point, and be it further

Resolved, That recent proposals to establish some form of compulsory health insurance in this state have come at the last minute without any

opportunity for adequate consideration and planning by any of the many interested groups or sufficient time for interchange of opinions and knowledge. Very considerable progress has been made in defining objectives in recent meetings between representatives of the medical profession with the governor and other groups, and it is the belief of your committee that such meeting and further exchange of ideas should be undertaken immediately and continued until a definite conclusion has been reached.

I move the adoption of this resolution as a whole.

It is further suggested that the California Medical Association specifically and immediately invite representatives of the government of the state of California, representatives of business and management interests, representatives of labor, representatives of agricultural organizations, representatives of the dental profession, representatives of hospitals and representatives of allied medical groups to joint conferences for the purpose of arriving at a complete and comprehensive plan to cover the entire problem of health service in California.

I move the adoption of this section of the committee's report.

During the deliberations of the committee, and from the study of the resolutions submitted, the committee has formulated certain basic principles that are inherent in the success of every prepayment plan of health service. These principles are fundamental. They may be enumerated as follows:

1. Absolute freedom of choice of physicians by the patient must be guaranteed.
2. Payments for service rendered must be on the basis of fee for service as opposed to capitation, in payment of the physician.
3. Unhampered medical control of all professional service.

I move the adoption of this section of the committee's report.

Medical Legislation

DISTRICT OF COLUMBIA

Bills Introduced.—S. 127, introduced by Senator Bilbo, Mississippi, and H. R. 317, introduced, by request, by Representative Randolph, West Virginia, propose to amend existing law relating to the registration of births in the District of Columbia. S. 223, introduced by Senator Radcliffe, Maryland, for Senator Tydings, Maryland, provides for the establishment of a modern, adequate and efficient hospital center in the District of Columbia.

MEDICAL BILLS IN CONGRESS

Bills Introduced.—S. 191, introduced by Senator Hill, Alabama, for himself and Senator Burton, Ohio, proposes an appropriation of \$110,000,000 to aid states in surveying their hospital and public health centers and in planning and constructing additional facilities. H. R. 1391, introduced by Representative Miller, Nebraska, proposes to establish a Department of National Health. H. R. 1284, introduced by Representative May, Kentucky, proposes to insure adequate medical care for the armed forces by providing for the registration, selection and induction of nurses. S. 190, introduced by Senator Murray, Montana, proposes to establish a National Institute of Dental Research in the United States Public Health Service to foster and aid in coordinating research relating to dental diseases and conditions. S. 178, introduced by Senator Murdock, Utah, proposes to amend the United States Employees' Compensation Act to permit chiropractors to treat beneficiaries of that act. H. R. 713, introduced by Representative Dickstein, New York, proposes to create in each corps area of the United States, as now constituted, a medical training school for the armed forces and the United States Public Health Service. H. R. 1120, introduced by Representative Murdock, Arizona, proposes that for pension purposes any person who served under contract with the War Department as acting assistant or contract surgeon between April 21, 1898 and Feb. 2, 1901 shall be considered to have been in the active military service of the United States for the period of such contract service between those dates. H. R. 550, introduced by Representative Somers, New York, proposes an appropriation of \$1,500,000 to construct a veterans' hospital in the borough of Brooklyn, city of New York, with a capacity of at least 500 beds. H. R. 611, introduced by Representative Tolan, California, provides for grants to states

for assistance in the rehabilitation of disabled persons incapacitated for normal employment H R 680 introduced by Representative Beckworth, Texas, proposes to amend the Social Security Act so as to provide grants to states for assistance to needy incapacitated individuals H R 686, introduced by Representative Bloom New York, proposes to amend the Federal Food, Drug and Cosmetic Act so as to declare a drug misbranded if it contains any quantity of boric acid or of any other substance which is poisonous when used internally and which is similar in appearance to another drug which is for use internally, unless it bears a label containing the statement "Warning—Poisonous If Used Internally" H R 1210, introduced by Representative Walter, Pennsylvania, proposes an appropriation of \$1 500,000 to construct a veterans' hospital in Pennsylvania, with a capacity of at least 400 beds

STATE MEDICAL LEGISLATION

Indiana

Bill Introduced—S 3, to supplement the medical practice act, authorizes for the duration of the war and eighteen months thereafter the issuance of a license without examination to any person honorably discharged from the armed forces who is a resident of the state, who subsequent to Dec 7 1941 graduated from an accredited medical school, who entered the armed forces before being licensed to practice medicine and who while in the armed forces practiced medicine

Iowa

Bill Introduced—H 15 proposes so to amend the narcotic drug act as to include within its purview isonipecaine, which is defined as "the substance identified chemically as 1-methyl-4-phenyl-piperidine-4 carboxylic acid ethyl ester, or any salt thereof, by whatever trade name identified"

Maryland

Bills Introduced—S 61, to amend the law requiring any physician, pharmacist, dentist hospital or nurse in Montgomery, Talbot Somerset and Worcester counties treating any person injured in an automobile accident or by a lethal weapon to report the fact to an appropriate police authority, proposes to make the requirement statewide H 60 proposes to authorize the state board of health to provide without charge for the treatment of persons exposed to hydrophobia The present law authorizes such treatment without charge only for those who are unable to pay the usual charges

Massachusetts

Bills Introduced—S 54 proposes to require a physician subsequent to the performance of an operation to deliver to the patient, or if a minor or an incompetent to the appropriate guardian, a written statement setting forth the nature of the operation performed and the physician's reasons for considering the operation necessary S 69 proposes to enact a separate chiropractic practice act and to create an independent board of registration of chiropractors to examine and license applicants for licenses to practice chiropractic The bill proposes to define the practice of chiropractic as "the science of locating, and removing, by hand only, interference with the transmission or expression of nerve force in the human body, where such interference is indicated or misalignment or subluxations of the vertebral column appear It excludes operative surgery, prescription or use of drugs or medicine, or the practice of obstetrics, except that the x-ray may be used solely for the purposes of examination" S 113 proposes to require every licensed physician annually to submit to an examination and test for syphilis and to display in his office a certificate stating the date and result of the last examination and test to which he submitted H 149 proposes to authorize, on the written application of a licensed physician, the admittance to North Reading State Sanatorium of a child suffering from rheumatic heart disease H 261 proposes to enact a law providing for a so called voluntary system for the payment of cash sickness, bodily injury, hospital, surgical operation and maternity benefits The bill proposes that every person employed in a private industry shall be eligible, unless he elects otherwise, to receive the benefits indicated above from his employer and the employer must

arrange for the payment of such benefits either by taking out an acceptable insurance policy or out of his own funds H 294 proposes to direct the department of mental health to construct and maintain an additional hospital for feebleminded children H 322, to amend the workmen's compensation act, proposes to require an employer to furnish to an injured employee, where necessary, glasses, artificial hearing devices and artificial dentures H 331 proposes to require a physician treating a patient suffering from cancer, sarcoma, leukemia primary tumors of the lymph nodes commonly classed as malignant lymphoma, or other malignant tumor to report to the department of public health the facts within one month after first obtaining knowledge thereof H 412 proposes to prohibit the sale, except on the written prescription of a licensed physician, dentist or veterinarian, of aminopyrine, barbituric acid, cinchophen, dinitrophenol, sulfanilamide and any other drug which has been found under the provisions of the federal food, drug and cosmetic act to be dangerous to health when used in the dosage or with the frequency or duration suggested in its labeling H 414 proposes, in effect, to authorize a chiroprapist or podiatrist to have in his possession any instrument adapted for the use of narcotic drugs by subcutaneous injection H 415, to amend the medical practice act, proposes that any applicant failing to pass an examination for licensure shall be permitted to take only two reexaminations and shall be required to pay an additional fee of three dollars for each reexamination H 416, to amend the medical practice act, proposes to authorize the board of registration in medicine in its discretion before issuing any certificate that has been revoked to require the physician concerned to pass a written examination to test his present fitness to practice

Michigan

Bill Introduced—S 6 proposes to authorize two or more cities, townships or incorporated villages or any combination thereof to incorporate a hospital authority for operating a community hospital

New York

Bills Introduced—S 2 proposes to continue until Feb 15, 1946 the temporary state commission heretofore authorized to survey the general question of medical care and to report its findings and recommendations to the legislature The bill further proposes to enlarge that commission to twelve persons, six of whom are to be licensed physicians, two laymen, one hospital administrator, one hospital nurse and one public health nurse S 60, to amend the medical practice act, proposes to authorize the board of regents to restore a license revoked because the holder thereof was convicted of a felony if the convicted physician receives a certificate of good conduct granted by the board of parole

Oklahoma

Bill Introduced—H 7 proposes to condition the issuance of a license to marry on the presentation by each party to the proposed marriage of a certificate from a licensed physician that within thirty days prior to the application for a license to marry the party has been given a standard serologic examination for syphilis and that in the opinion of the physician he or she is not infected with syphilis or, if infected, is not in a stage that may be communicable to the prospective marital partner

Washington Letter

(From a Special Correspondent)

Jan. 15, 1945.

President Asks National Service Law

Enactment of a National Service Law to meet the manpower crisis was advocated by President Roosevelt in his annual message, read to a joint session of the House and Senate. He asked specifically for speedy passage of legislation to induct nurses and the four million 4-F men. He also urged extended social security, health and education programs. In his domestic program he emphasized (1) adoption of universal military training after the war; (2) full employment after the war, with greatest possible use of private enterprise to provide his promised 60,000,000 jobs; (3) assurance of chances for new small enterprises and business expansion with government guaranteed financing; (4) development of national resources and a large public works program as part of the full employment project; (5) provision of better housing with cooperation of industry, labor and federal, state and local governments; (6) expanded social security health and education programs, and (7) peacetime revision of the present tax structure "to encourage private demand."

Gas "Prescriptions" Used in Capital

So serious is the shortage of gasoline in Washington that certain service stations have been designated specifically to serve only doctors and nurses, who can get gas on submission of their signed "prescriptions." This procedure follows in part recommendations, made when the shortage reached a critical stage, by District of Columbia Coroner A. Magruder McDonald, executive member of the District Medical Society, who called on government officials to (1) earmark part of the city's gasoline allocation for exclusive consumption by doctors, (2) designate certain stations as distributors of this gas and (3) arrange for physicians to get preferential treatment at all stations, including provisions for the purchase of gas at specified hours both day and night. Doctors reported that patients went untreated when they were unable to make calls through lack of transportation.

Thirty-Nine Million Americans Under Social Security Insurance

Acting Federal Security Administrator Watson B. Miller has announced that more than 39,000,000 American men and women have entered 1945 with insured status in the old age and survivors insurance program of the Social Security Act. Under the old age and survivors insurance program, the monthly benefit rolls rose to 1,120,000 men, women and children, eligible to receive \$20,500,000 monthly. Monthly benefit payments were awarded to 324,000 new applicants last year, and lump sum benefit payments were made to 208,000 survivors of insured workers who left no one immediately entitled to monthly benefits. Estimated totals certified for 1944 were \$196,100,000 in monthly benefits and \$22,400,000 in lump sums.

Scientific Roster Helps Medical World

The National Roster of Scientific and Specialized Personnel, which according to Paul V. McNutt, chairman of the War Manpower Commission, has placed approximately 50,000 persons since its founding in June 1940, has been of inestimable help in the medical field, it is revealed here. An example: One company engaged in research on penicillin asked for a mycologist who was a specialist in fungus growth that might prove to be sources of this medicine and other drugs needed for treatment of war wounds. The roster made an intensive search of its records and obtained the employee by the transfer system. Mr. McNutt said that the medical profession had cooperated closely with the Roster.

Induction of "Remediable" 4-Fs Proposed

A conference of interested governmental agencies to study the possibilities of rehabilitating 750,000 4-F draft registrants for military service has been proposed by Senator Claude Pepper, Democrat of Florida, chairman of the Senate Subcommittee on

Wartime Health and Education. He suggested three courses: (1) induction of unessentially employed 4-Fs with remediable defects for corrective treatment at government expense under the Selective Service Administration; (2) expansion, if feasible, of the Army's rehabilitation program; (3) expansion of state rehabilitation programs now operated with federal aid under the Barden-La Follette act. Senator Pepper said that testimony before his subcommittee showed that one sixth of the 4,500,000 4-Fs could be made fit for active service.

Two UNRRA Sanitary Conventions Signed

Two international sanitary conventions facilitating operations of the United Nations Relief and Rehabilitation Administration were signed in Washington this week by Lord Halifax, British ambassador to the United States, Professor André Mayer, medical counselor of the French Provisional Government in the United States, Secretary of State Stettinius, Jan Ciechanowski, Polish ambassador, and Herbert H. Lehman, director general of UNRRA. The conventions concern maritime and aerial travel. They amend the international maritime sanitary convention signed in Paris in 1926 and the international sanitary convention for aerial navigation signed at The Hague in 1933.

Twenty-Eight Million Army Bandages Sold as Dusters

Twenty-eight million U. S. Army first aid dressings were offered for sale by the Treasury Department for use as dust cloths, although the bandages, wrapped separately in containers, are as good as new. The army surgeon general's department explained that the bandages do not conform in size and type with dressings now deemed more efficient. Resale of the bandages for medical use is forbidden under terms of the sales contract, and Treasury spokesmen said they could have "such uses as dust cloths, window wipers and machinery wiping cloths."

Government Appeals for Citizen Cooperation

Uncle Sam today asked his people in this 461st week of the war to help send 10,000 urgently needed army nurses to the fighting front by volunteering as Red Cross nurse's aides and to donate 100,000 pints of blood to meet the quota being flown to wounded men in Europe and the Pacific. Drastic action is already forecast in Congress or by executive action to correct the shortage of nurses for the armed forces. If Congress is asked to legislate, nurses will probably demand that they be given military rank, with benefits enjoyed by the women's services.

Official Notes

NBC RADIO BROADCASTS

The American Medical Association and the National Broadcasting Company are presenting the twelfth consecutive season of nationwide network health broadcasts, which began January 6 and will continue through June 30. The title of the series for 1945 is *Doctors Look Ahead*. Included in the series are broadcasts relating to wartime and postwar developments, with special emphasis on medical progress of the present day and what it foreshadows for the nation's health in the immediate future.

Topics will be announced weekly in *THE JOURNAL* and monthly in *Hygieia*. Fast moving events may, however, cause last minute substitution of topics. Local newspapers should be consulted for announcements of time and stations. The program will be broadcast each Saturday at 4 p. m. Eastern War Time (3 p. m. Central, 2 p. m. Mountain and 1 p. m. Pacific War Time). When conflicts exist with local programs, rebroadcasts may be arranged at hours other than on the network schedule. The following are the topics for January:

January 20, Sulfa Drugs (Dr. Austin Smith).
January 27, Penicillin (Dr. Austin Smith).
February 3, Social Hygiene.

The broadcast will be under the supervision of the Bureau of Health Education, whose director, Dr. W. W. Bauer, will summarize each program except when other speakers are announced.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

DELAWARE

Personal.—Dr. Mary Putnam, field physician of the Wisconsin State Board of Health, has been appointed pediatrician to the Delaware State Board of Health to direct the baby clinics carried on by the board in the state each month and to handle several crippled children's clinics. Dr. Putnam succeeds Dr. Marion S. S. Dressler, resigned.

DISTRICT OF COLUMBIA

Hospital News.—Ground was broken December 18 for the new Georgetown University Hospital, which is expected to be completed in January 1946. The building will contain 400 beds and be constructed at a cost of \$2,420,000. The Federal Works Agency has allotted \$1,820,000 toward the cost.

New Health Council.—The Washington Metropolitan Health Council was recently created under the sponsorship of the health division of the Council of Social Agencies. One of its first activities will be a comprehensive survey of health and hospital facilities in Washington. Admiral Ross T. McIntire, Surgeon General of the Navy, is chairman of the survey committee. Dr. Herbert P. Ramsey is head of the health division of the Council of Social Agencies.

Plan to Form Diabetic Association.—The executive board of the Medical Society of the District of Columbia and the committee on public health recently adopted recommendations sent to them by a group of physicians asking for an educational and preventive medicine program for the diabetic patients in Washington. According to *Medical Annals* it is proposed that statistics from all possible sources about the diabetic in Washington be gathered preliminary to the formation of a diabetic association, the object of which would be the education of the diabetic patient, physicians, nurses, dietitians, and others interested in diabetes. When the statistical data have been analyzed, announcement will be made concerning the formation of the proposed diabetic association.

IDAHO

Society News.—The Idaho Hospital Association held its annual meeting at the Owyhee Hotel, Boise, Dec. 9, 1944, at which 22 delegates represented ten hospitals. Mrs. Helen B. Ross, St. Luke's Hospital, Boise, was elected president and Nelson Ammons, business manager of Samaritan Hospital, Nampa, was chosen secretary-treasurer.

Hospital News.—The Gooding Chamber of Commerce is sponsoring a plan to enlarge the Gooding County Hospital, proposing to increase its capacity from 16 to 40 beds. Other changes will bring the proposed cost to about \$50,000. Funds have been collected and a site chosen for a new hospital at Jerome, to be located on the Shepherd estate on North Lincoln Avenue and to cost about \$100,000, according to *Northwest Medicine*.

ILLINOIS

New Chief of Maternal and Child Hygiene.—Dr. Henrietta M. Herbolzheimer has been appointed chief of the division of maternal and child hygiene in the state department of public health, effective January 1. During the previous six months she filled this position as acting chief, after having been promoted from a staff position which she had held since May 1942 (*THE JOURNAL*, July 22, 1944, p. 858).

Chicago

Francis Blake to Discuss Penicillin.—Dr. Francis G. Blake, dean, professor and head of the department of medicine, Yale University School of Medicine, New Haven, will discuss "Three Years' Experience with Penicillin Therapy" at a meeting of the North Side branch of the Chicago Medical Society in the Drake Hotel, February 1.

Society of Bacteriologists.—The Society of Illinois Bacteriologists will be addressed at the Museum of Science and Industry, February 9, by:

Dr. Katharine M. Howell and Elta Knowl, B.S., Studies on *Dientameba Fragilis* and Its Incidence and Possible Pathogenicity.
Werner Baumgarten, Ph.D., Peoria, Ill., Microbiologic Determination of Amino Acids.

Dr. Israel Davidsohn, The Rh Factor and Its Practical Applications.

Colonel Rusk to Give Billings Lecture.—Col. Howard A. Rusk, M. C., chief, convalescent training division, Office of the Air Surgeon, will deliver the sixth Frank Billings Lecture of the Thomas Lewis Gilmer Foundation of the Institute of Medicine of Chicago in the Grand Ball Room of the Drake Hotel, February 12. His subject will be "Rehabilitation—The Challenge to American Medicine." The lecture will be a feature of the institute's midwest conference on rehabilitation.

Orthopedic Meeting.—On January 19 the Chicago Orthopaedic Society was addressed at the Palmer House by Drs. Allen F. Voshell, Baltimore, on "Some Clinical Implications Based on Internal Knee Joint Anatomy"; Le Roy C. Abbott, San Francisco, "Surgical Approaches to the Knee Joint," and Guy A. Caldwell, New Orleans, "Factors Concerned in Delayed Healing of Wounds." Other speakers on the program included Drs. James S. Speed, Memphis, Tenn., and Joseph A. Freiberg, Cincinnati.

Prevalence of Ringworm.—The Chicago Board of Health is conducting a survey to determine the number of children in Chicago affected with ringworm, because of the indications that the disease among children of all ages up to 14 seems in some places to be reaching epidemic proportions. The reports indicate that the disease has affected six times as many boys as girls. In a release to the press, Dr. Herman N. Bundesen, president of the board of health, stated that the spread of the disease is apparently associated with many factors related to the war, such as overcrowding, increased travel and neglect resulting from increased employment and responsibilities of parents. The release stated that in other communities such as New York, St. Louis, Flint, Mich., and Pittsburgh the following suggestions have been made to combat the spread of the infection, among other measures:

Routine examination of the scalp of all children, by using a special type of light which makes the disorder at once apparent.

Insistence on the wearing of a protective paper or cloth cap by the children infected until cured.

Avoidance of exposure, particularly of the back of the head, to the backs of seats much used by other children, as in all places of public assemblage.

Efficient medical treatment of every infected child until pronounced free from infection.

MASSACHUSETTS

License Revoked.—The state board of registration in medicine on November 17 revoked the license of Dr. Samuel Greenstein, Dorchester and Boston, because "of gross misconduct in the practice of his profession as shown by collusion."

Double Anniversary in Massachusetts Health.—On December 6 the Massachusetts Department of Public Health observed the seventy-fifth anniversary of its establishment and the fiftieth anniversary of the establishment of its state antitoxin laboratories. In 1869 the Massachusetts legislature passed an act to establish a state board of health, the first in America. The anniversary program includes a morning session at the Peter Bent Brigham Hospital, Boston, a buffet luncheon at the antitoxin laboratory, afternoon and evening meetings at Ford Hall and dinner at the Parker House.

Changes in Health Personnel.—Dr. George E. Perkins, Boston, has been appointed acting director of the division of venereal diseases of the Massachusetts Department of Public Health to succeed John B. Hozier, P. A. Surg., U. S. Public Health Service, who has been recalled to Washington. Dr. Perkins served as lieutenant colonel in the medical corps of the army until his retirement in November. Prior to his retirement he was a medical consultant with the rating boards under the Veterans Administration, serving in this capacity at the Bronx, New York; Atlanta, Ga., and Togus, Maine. Dr. James W. Knepp, formerly post medical inspector at Camp Edwards with the rank of lieutenant colonel in the army, has been appointed health officer of the Worcester district of the state department of health. Dr. Knepp has retired from the army.

MINNESOTA

Tenth County Accredited for Tuberculosis Control.—Jackson County is the tenth county in the state to be credited for the control of human tuberculosis. Accreditation ceremonies were held in Jackson November 16. The certification indicates that the county has met the minimum requirements of the state department of health and the Minnesota State Medical Association for the control of tuberculosis.

Directorship of Health Education Created.—D. Clare Gates, Dr.P.H., has been appointed to a newly created position of director of health education in the Minneapolis City Health Department, according to Dr. Frank J. Hill, health commissioner. Although the civil service appointment began January 1, Dr. Gates has filled the position since November 1 through a financial grant from the Hennepin County Tuberculosis Association. Dr. Gates received his degree in public health at the University of Michigan in 1937.

School of Public Health at Minnesota.—The regents of the University of Minnesota Medical School, Minneapolis, recently changed the status of the department of preventive medicine and public health to the School of Public Health. The change was made to give proper recognition to a department which has been for a number of years offering professional training in public health for physicians, engineers and nurses and more recently for health educators. The School of Public Health will continue to function as an integral part of the medical school and the university Division of Medical Sciences. A building program planned at the university eventually will include a separate unit for the School of Public Health (THE JOURNAL, January 13, p. 111). Dr. Gaylord W. Anderson, professor and head of the department of preventive medicine and public health, on leave of absence as lieutenant colonel, medical corps, Army of the United States, and chief of the division of medical intelligence, Office of the Surgeon General, has been named director of the new School of Public Health. On January 2 Dr. Haven Emerson, New York, returned to the medical school as visiting professor of public health to serve, according to present plans, for the year 1945. During the leave of Dr. Anderson, Dr. Emerson has served in a similar capacity.

NEBRASKA

New Officers of Clinical Society.—At the annual meeting of the Omaha Mid-West Clinical Society, December 11, Dr. Joseph D. McCarthy was chosen president-elect and Dr. J. Jay Keegan was installed as president. Dr. Roy W. Fouts was elected secretary, and director of clinics and Dr. John M. Thomas assistant secretary.

NEW JERSEY

Unit for Children with Chronic Heart Disease.—The Hospital and Home for Crippled Children, Newark, recently opened a wing as a separate unit for the care of children crippled with heart disease.

Personal.—Clarence T. Van Meter, Ph.D., assistant professor of chemistry and physics at the school of pharmacy of the University of Pittsburgh, has become scientific director of the physiologic laboratories of Reed and Carnrick, Jersey City, according to *Science*.

Society of Surgeons.—The annual meeting of the Society of Surgeons of New Jersey will be held in Jersey City, January 31, at the Jersey City Hospital. Among the speakers will be:

- Dr. Frank Bortone, Jersey City, Esophageal Diverticula.
- Dr. Louis C. Lange, Weehawken, Gallstone Ileus and Internal Biliary Fistulas.
- Dr. Earl J. Halligan, Jersey City, Treatment of the Remaining Common Dust Stone.
- Dr. Edgar Burke, Jersey City, Case Presentations of Unusual Surgical Interest.
- Dr. Edward G. Waters, Jersey City, Presacral Sympathectomy for Functional Uterine Pain—Its Selective Usefulness.
- Dr. Stanley R. Woodruff, Jersey City, Surgical Treatment of Urinary Incontinence in Certain Congenital Anomalies.
- Dr. Samuel A. Cosgrove and Leon C. Chesley, Ph.D., Jersey City, Management of the late Pregnancy Toxemias.
- Dr. Walter B. Mount, Montclair, Certain Trends in Obstetric Forceps.

NEW YORK

William D. Coolidge Retires.—On December 31 Dr. William D. Coolidge, who has an honorary degree of doctor of medicine from the University of Zurich, retired as vice president and director of research in the General Electric Company, Schenectady. Dr. Coolidge was born in Hudson, Mass., Oct. 23, 1873. He received his B.S. from the Massachusetts Institute of Technology and his Ph.D. from the University of Leipzig in 1899. The honorary M.D. was given to him by Zurich in 1937. He is a fellow of the American Association for the Advancement of Science and an honorary member of a number of roentgen ray societies. Chauncey G. Suits, D.Sc., assistant to the director of research, has been elected a vice president of the company and has been placed in charge of the research laboratory.

New York City

University News.—Columbia University College of Physicians and Surgeons has received a grant of \$14,500 from the Commonwealth Fund of New York to be applied to the study of respiratory physiology in the department of medicine.

Dr. Napier Named Visiting Professor of Tropical Medicine.—Dr. L. Everard Napier, formerly director of the School of Tropical Medicine of Calcutta, India, has been appointed visiting professor of tropical medicine at the New York University College of Medicine for the months of Jan-

uary and February of 1945. This has been made possible by a grant received from the Commonwealth Fund. During this time Dr. Napier will give several special lectures to the faculty and student body and will hold conferences with students.

New York Medicine.—On January 5 *New York Medicine* made its appearance, supplanting the *Journal of the Medical Society of the County of New York*. The bulletin will be published on the 5th and the 20th of each month throughout the year and will have the subtitle "Official Bulletin of the Medical Society of the County of New York." An announcement indicates that in general the editorial policy of the journal will be maintained without spectacular alteration, but it is planned to develop gradually a working editorial board representative of various aspects and institutions of medical practice.

Health in New York City.—In 1944 the general death rate for New York City was 10.3 per thousand of population as compared with 10.9 in 1943. This rate compares with the record low of 9.9 for the year 1941. The city registered its lowest maternal mortality rate in 1944 (1.8 per thousand live births) as against a rate of 2.2 for 1943. New low death rates were also recorded for tuberculosis, which totaled 3,533 deaths in 1944, appendicitis, whooping cough, automobile accidents, other accidents and suicides. The infant mortality rate showed an increase for the second consecutive year from 30.2 per thousand live births in 1943 to 31.2 in 1944. There were 7 deaths from diphtheria in 1944 as against 16 in 1943, with the total number of cases from this disease constituting an all time low mark of 242.

OHIO

The Offices of Doctors in Service.—The *Bulletin of the Toledo Academy of Medicine* recently praised the action of a number of Toledo building managers for their way of handling the offices of physicians until their return from military service. Many of the buildings are holding doctors' offices until they return from the service. In some cases offices have been locked and the equipment left intact. Some managers charge a nominal rental and others none at all. The council of the Toledo Academy of Medicine at a recent meeting voted to express its appreciation to these building managers for the splendid cooperation they have given to physicians.

New Cancer Project at Western Reserve.—With gifts of about \$15,000, a new cancer research project will be launched at Western Reserve University School of Medicine, Cleveland, to investigate the curative properties of a serum evolved by Dr. Alexander A. Bogomolets, director of the institute of experimental biology and pathology in the Soviet Union. The work will be carried out under the direction of Dr. Harry Goldblatt, associate director of the institute of pathology at the medical school, who, with Enrique E. Ecker, Ph.D., professor of immunology, has been interested in the serum. Of the funds, \$4,000 has been obtained from the Herbert Jules Goodman Foundation created by Mr. and Mrs. Harry Kirtz and Mr. and Mrs. Jules A. Goodman of Cleveland. Herbert Jules Goodman, Mrs. Kirtz's only child, died of cancer on Feb. 4, 1944. To the fund for this work, initiated by the Herbert Jules Goodman Foundation, the Elizabeth Severance Prentiss Foundation has added \$4,000, the Field Army of the American Cancer Society is donating \$3,000, the Cleveland Foundation \$1,000 and the Louis D. Beaumont Trust \$1,000. The Field Army plans to raise \$2,000 more. Dr. Bogomolets, in his description of the serum in the *American Review of Soviet Medicine*, December 1943, claimed that the serum is effective not only against cancer but against high blood pressure and arthritis, claiming that it increases the power of the body to fight off infectious disease and promote wound healing and that it will even prolong life. Dr. Goldblatt's interest stemmed from his work on high blood pressure and his interest in cancer and Dr. Ecker because of his research in the role of blood complement in resisting infection. In a release to the press it was stated that similar work is now being conducted at the Cedars of Lebanon Hospital, Los Angeles, under the direction of Dr. Reuben K. Straus, formerly chief pathologist in the coroner's office of Cuyahoga County, Cleveland, and a former student of Dr. Goldblatt.

PENNSYLVANIA

Philip Woodbridge Joins Reading Hospital.—Dr. Philip D. Woodbridge has resigned as professor and head of the department of anesthesiology, Temple University School of Medicine and Hospital, effective January 6, to become head of the department of anesthesiology at the Reading Hospital, Reading. The new appointment was to be effective about January 16.

Philadelphia

Fifty Years of Medicine.—On January 9 the following members of the Philadelphia County Medical Society were given certificates by the Medical Society of the State of Pennsylvania testifying to the completion of fifty years in the practice of medicine:

Dr. Miriam M. Butt	Dr. W. Hersey Thomas
Dr. Irving W. Hollingshead	Dr. Frederick J. Voss
Dr. Harry A. Shute	Dr. George B. Wood
Dr. William S. Wray	

These physicians, in addition to a number of others (THE JOURNAL, Dec. 30, 1944, p. 1160), were guests at a councilor district luncheon meeting at the Philadelphia County Medical Society.

Pittsburgh

Personal.—Dr. William S. McEllroy, dean of the University of Pittsburgh School of Medicine, has been appointed medical survey adviser to succeed Dr. Charles R. Reynolds, Chicago.

Frederick Fagler Named Secretary of Allegheny County.—Mr. Frederick W. Fagler on January 1 became executive secretary of the Allegheny County Medical Society. Mr. Fagler was formerly assistant sales manager of the Hotel Statler Company, Inc., and has been located for the last three years at the William Penn Hotel, Pittsburgh. He fills the vacancy that occurred when Dr. George R. Harris resigned (THE JOURNAL, Aug. 12, 1944, p. 1050).

Daniel Braun Named to Head New Department.—Dr. Daniel C. Braun, Mount Lebanon, since September 1938 medical examiner for the Pittsburgh Coal Company, has been appointed medical director of the company's newly created department of industrial medicine. The new unit was organized to provide better supervision of the health of company employees and research into medical problems peculiar to coal mining. Dr. Braun graduated at the University of Pittsburgh School of Medicine in 1937. He took postgraduate work in industrial hygiene at Pittsburgh in 1941 and the Long Island College of Medicine, Brooklyn, in 1942 and participated in special classes sponsored by the Allegheny County Medical Society the same year.

TENNESSEE

Medical School Graduates in Second Generation at Vanderbilt.—One fourth of the recent 52 graduates of Vanderbilt University School of Medicine, Nashville, were in the "Vanderbilt Tradition," 13 were second generation "Vanderbilters" and 2 of these were grandsons of Vanderbilt alumni.

WISCONSIN

Dr. William Beaumont Memorial Foundation.—A brochure on the career of Dr. William Beaumont has been released by the memorial foundation created in 1943 (THE JOURNAL, Oct. 2, 1943, p. 297) to honor the physiologist. The pages show the officers and personnel of the foundation and contain illustrations and historical material to memorialize Dr. Beaumont. The booklet is available on request to the Dr. William Beaumont Memorial Foundation, Prairie Du Chien.

Research for Penicillin.—The University of Wisconsin, Madison, is sponsoring research on penicillin in three of its departments, biochemistry, agricultural bacteriology and botany. The work is being carried out under the auspices of the Office of Production Research and Development of the War Production Board and is in addition supported by grants from various companies which produce penicillin, including the Heyden Chemical Corporation, New York, which has contributed \$4,400, and Lederle Laboratories, Inc., Pearl River, N. Y., which has contributed \$4,800. Funds have also been given by the Wisconsin Alumni Research Foundation, according to Science.

GENERAL

Special Society Election.—Dr. William G. Lennox, Children's Hospital, 300 Longwood Avenue, Boston, is president of the Association for Research in Nervous and Mental Diseases, which held its annual meeting in New York December 16. Other officers include Drs. H. Houston Merritt, Boston, and Wilder G. Penfield, Montreal, Que., vice presidents, and Thomas E. Bamford Jr., New York, secretary-treasurer. The society agreed to devote its program for its 1945 session to the subject of epilepsy and convulsive disorders.

Physician Swindled.—A physician in Newport, Ky., recently announced that he had not received delivery on an order for which he gave part payment to a so-called representative of the Manhattan Manufacturing Company, Chicago. On inquiry to the company the physician was told that it had no salesman using the name of L. H. Lancaster which appears

on the receipt and that presumably the impostor was one who had been employing a similar swindle in Western states. The company states that an authorized representative would have official order books and not a blank form on which any company's name could be written.

March of Dimes.—The 1945 March of Dimes was officially opened January 14 with a special coast to coast broadcast made by Mr. Basil O'Connor, president of the National Foundation for Infantile Paralysis, and J. Harold Ryan, president, National Association of Broadcasters, and also chairman of the national radio division of the March of Dimes. The appeal for funds will be climaxed by birthday parties and other celebrations on President Roosevelt's birthday, January 30, and will conclude January 31. For the first time the initial rally of the March of Dimes drive in New York City was a national affair, the program taking place at the Rockefeller Center, January 15. Other features incident to the annual campaign for funds was a specially dramatized broadcast of the infantile paralysis epidemic in North Carolina this past summer.

Physician Wins Prize for Work on "The Doctor's Job."—Dr. Carl A. L. Binger, assistant professor of clinical medicine (psychiatry), Cornell University Medical College, New York, is the recipient of the first Norton Medical Award of \$3,500 offered to encourage the writing of books on medicine and the medical profession for the layman. The title of Dr. Binger's book is "The Doctor's Job," which will be published March 26. The book undertakes to put the lay public in living touch with the medical world as it exists today. Dr. Binger graduated at Harvard Medical School, Boston, in 1914 and served for a time with the Rockefeller Institute for Medical Research. W. W. Norton & Company, sponsors of the prize, announces that a similar award is again offered for a book to be published in 1946. Further details may be obtained from the W. W. Norton & Company, Inc., Medical Award, 70 Fifth Avenue, New York 11.

Ella Sachs Plotz Foundation.—The twenty-first annual report of the Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation indicates that of the twenty-seven applications for grants received during the year nineteen came from the United States, the other eight coming from five different countries in Europe, Asia and South America. During its twenty-one years the foundation has made 508 grants to scientists throughout the world. Applications for grants to be held during the year 1945-1946 must be received by the executive committee before April 1945. There are no formal application blanks, but letters asking for aid must give definitely the qualifications of the investigator, an accurate description of the research, the size of the grant requested and the specific use of the money to be expended. In their requests for aid, applicants should state whether or not they have approached other foundations for financial assistance. Applications should be sent to Dr. Joseph C. Aub, Massachusetts General Hospital, Fruit Street, Boston 14.

Planned Parenthood Meeting.—"Responsibility for the Health of Tomorrow's Family" will be the theme of the twenty-fourth annual dinner meeting of the Planned Parenthood Federation of America at the Waldorf-Astoria, New York, January 24. The speakers will be Ralph C. Williams, assistant surgeon general in charge of the Bureau of Medical Services, U. S. Public Health Service; Lieut. Col. Roy R. Grinker, M. C., and Dr. Edward A. Schumann, Philadelphia. At a luncheon of other agencies January 23 "The Future of the American Family" will be the subject of a symposium at which Mrs. Franklin D. Roosevelt will be the speaker. Topics for discussion at other sessions will be "Summing Up a Year's Work," "How to Achieve Teamwork Between Board Members and Staff," "Organizing and Interpreting Planned Parenthood into Effective Action," "Applying Tested Principles in Interpreting Planned Parenthood to Professional Groups," "To the Medical Profession," "To Clergymen," "Steps Toward Increasing Negro Participation," "Interpreting Planned Parenthood to the Everyday Citizen" and "How to Obtain Financial Support to Put Our Programs into Action."

National Sanitation Foundation Organized.—The creation of the National Sanitation Foundation was announced on January 2. Henry F. Vaughan, Dr.P.H., dean of the School of Public Health of the University of Michigan, will serve as president of the new foundation, which has been chartered in Michigan with headquarters at the School of Public Health, Ann Arbor, to promote progress and betterment in environmental sanitation, health and education. The foundation will be concerned with the advancement of scientific research, experiments, demonstrations, evaluations and the practical application of new and coordinated knowledge in the field of

environmental sanitation. Studies in food sanitation and food handling technics will receive early consideration. Selected studies sponsored by colleges, universities and public health agencies and departments of federal, state and local governments will receive material aid. The work of the foundation is financed by gifts and contributions from manufacturers, distributors and other individuals and groups interested in the promotion of environmental health. The officers of the foundation, in addition to Dr. Vaughan, who is president, are Nathan Sinai, Dr.P.H., professor of hygiene and public health at the University of Michigan, vice president, and Walter F. Snyder, former chief of the bureau of sanitation of the Toledo, Ohio, health division, executive director.

National Conference on Medical Service.—"Distribution of Medical Care" will be the theme of the National Conference on Medical Service during its meeting in the Palmer House, Chicago, February 11. Dr. Chauncey L. Palmer, Pittsburgh, will deliver the presidential address on "Medicine and the National Crisis." Other speakers will be:

Walter P. Reuther, vice president, United Automobile Workers, C. I. O., Detroit, What Labor Expects from Medicine.

Roger B. Corbett, Ph.D., executive secretary, American Farm Bureau Federation, Chicago, What the Farmer Expects from Medicine.

Harlan S. Don Carlos, manager, life, accident and group claim department, Travelers Insurance Company, Hartford, Conn., What the Insurance Man Expects from Medicine.

Hon. A. L. Miller, Washington, D. C., Congressman from Fourth District, Nebraska, The Miller Bills and Medical Legislation by Congress.

Dr. John H. Fitzgibbon, Portland, Ore., Public Relations Program of the American Medical Association.

Lieut. Col. Harold C. Leuth, M. C., Changes in Attitude of Medical Officers Toward Medical Education and Practice.

There will be an open discussion on prepayment of medical insurance plans with Dr. Creighton Barker, secretary, Connecticut State Medical Society, New Haven, acting as the moderator.

LATIN AMERICA

Health Activities in Latin America.—*Tuberculosis in Haiti.*—The Bulletin of the National Tuberculosis Association points out that 1,500 x-ray examinations and fluoroscopies in Haiti show that an average of 19 per cent of persons with positive skin reaction show tuberculous lesions, active or inactive. The National Antituberculosis League (THE JOURNAL, Dec. 16, 1944, p. 1042) was organized to assist in improving the situation. It is a private organization recognized by official agencies and supported by the country as a whole and by the government. In the recent first antituberculosis week \$35,000 was raised by popular subscription, which helped defray the new \$32,000 100 bed sanatorium, for which twelve doctors and ten nurses have been trained to work there and in the clinics.

Personal.—Reuben L. Kahn, Sc.D., Ann Arbor, Mich., discoverer of the Kahn test for syphilis, announced to the press in Puerto Rico recently that he is working on a new test that seeks to discover latent malaria in soldiers in tropical war zones that may prevent their being returned home with the disease undetected. Dr. Kahn also disclosed that he is in Puerto Rico to aid health officers in one of the problems that obstruct work toward suppression of venereal disease. Dr. Kahn will be in Puerto Rico several days through the cooperation of the Anglo-American Caribbean Commission.—Dr. Emmanuel Dias of the Instituto Oswaldo Cruz, Rio de Janeiro, is in charge of the first experimental station for the prevention of Chagas' disease in South America. The station is in Banbui, west of Minas Gerais. In the six months during which the station has been operating, nearly 15,000 triatomines have been captured or killed. *Tropical Medicine News* states that all kinds of insecticides are being tested and that pyrethrum and DDT seem to be the most satisfactory.

Decrease in Malaria.—Nicaraguan health authorities say the malaria index is lower this year than in the last twenty years because of the sanitation work conducted by Nicaraguan and United States health authorities, the New York Times reported.

FOREIGN

Nuffield Grant for Industrial Health.—The trustees of the Nuffield Foundation have offered the universities of Durham, Glasgow and Manchester grants totaling \$600,000 to carry out schemes which they have submitted for the development, as soon as suitable staffs can be appointed, of teaching and research in industrial health. These grants will be spread over a ten year period.

Conway Evans Prize.—Sir Thomas Lewis, physician, University Hospital, has been awarded the Conway Evans prize by the Royal Society and the Royal College of Physicians in recognition of his contribution to medical knowledge

on the normal and abnormal mechanisms of the heart and circulation of the blood. This prize, in accordance with the will of the late Dr. Conway Evans, who was medical officer for the Strand district, is awarded from time to time for scientific work of distinction. According to the *British Medical Journal* it was given first to Sir Charles S. Sherrington in 1927 and then to the late Dr. John S. Haldane in 1933 and to Sir Frederick Gowland Hopkins in 1938.

Alcohol Production in Diabetes.—A report on the investigations of Dr. Jakob W. S. Möllerström, department for metabolic research at the Wenner-Gren Institute of Stockholm, reveals that a certain amount of free alcohol is always present in the blood of a diabetic person, who is consequently more or less intoxicated. In his investigations into the different methods employed to measure the content of alcohol in the blood, which are used by the police in examining persons involved in traffic accidents, he found that two standard methods used, when applied to a case of manifest diabetes, gave figures which varied between 0.035 and 0.5 per cent. According to Dr. Möllerström the reason seems to be that the alcohol generated by the body is mostly bound to certain albumins and is therefore in part undemonstrable through analysis by the standard methods. It is known that the blood of a person with diabetes contains so-called acetone bodies, which influence the result of the alcohol analysis. The presence of such bodies can be determined by specific examination, and a certain allowance is made in cases in which they appear. Dr. Möllerström now definitely asserts that the human body can produce considerable quantities of alcohol even though such bodies are not found in the blood of the patient. The discovery appears to be a very important one, both for the treatment of diabetes and for the legislation concerning alcohol consumption in connection with traffic accidents. A person may present a percentage of alcohol which would be high enough to have him punished for abuse of alcohol, whereas in actual fact he may be suffering from diabetes.

CORRECTION

Washington Letter.—The remarks of Brig. Gen. James S. Simmons, Dr. Lewis H. Weed and other medical authorities under "Importance of Postwar Research Stressed" in the Washington Letter (THE JOURNAL, Dec. 23, 1944, p. 1093) should have been assigned to testimony before the Senate Committee on Wartime Health and Education rather than to the Kelley subcommittee.

Government Services

National Program of Maternal and Child Health Services

Dr. Martha M. Eliot, associate chief of the Children's Bureau, Department of Labor, reported on January 7 that seventy physicians and professional workers, meeting in Washington as an advisory committee to the Children's Bureau, had endorsed "a nationwide survey of personnel and facilities needed to assure health services to all mothers and children, which will be undertaken by the American Academy of Pediatrics, with the help of the Children's Bureau and the U. S. Public Health Service." Chairmen of the advisory committee were Dr. Nicholson J. Eastman, professor of obstetrics at the Johns Hopkins University School of Medicine, Baltimore, and Dr. Henry F. Helmholz, head of the pediatric section of the Mayo Clinic, Rochester, Minn. The plan would tie in closely with the postwar "health center" network recommended by the Pepper subcommittee on wartime health and education and would establish for each state statistics on distribution of children in rural and urban areas; number and distribution of pediatricians and number of general practitioners graduated since 1930; number of hospital facilities, health centers, antepartum clinics and well child conferences already established and the method and rate of pay of professional personnel in these services; number of county and district health departments; the status of public health and pediatric nursing; provisions for social services to make curative care available, and status of school health services. The advisory committee on maternal child health set up as its aim "a long-term program directed at lowering maternal and child mortality and morbidity to an irreducible minimum" and advocated "the delivery of all women in good hospitals under the care of competent physicians."

Foreign Letters

LONDON

(From Our Regular Correspondent)

Dec. 16, 1944.

The British Medical Association and the Government Health Service

The annual representative meeting of the British Medical Association is described by the *British Medical Journal* as one of the most momentous in its history. For four days nearly 270 representatives from all parts of the British Isles discussed the government's White Paper for a comprehensive medical service for the whole population. Three hundred and seventy separate motions were debated. These all consisted of objections to various proposals in the White Paper, and in general they were carried. But those which involved rejection of the whole scheme were not carried; it was decided instead to negotiate with the government. The negotiators were to press for the best service which could be established. A comprehensive medical service should be available to all who need it, the sense of the resolutions held, but it is unnecessary for the state to provide for those who are willing and able to provide it for themselves. Every man, woman and child should be able to rely on getting all the treatment and cure that may be needed. But grave concern was expressed at the proposals to place the administration of the service under the Ministry of Health and local authorities, and a demand was made for a thorough and impartial inquiry into the proposed administrative structure. Any interference of government in the doctor-patient relationship would be resisted, the representatives declared. Local authorities were totally unsuitable for the control of medical matters, it was emphasized. In the event of the establishment of advisory councils, the meeting was in favor of a single local health service council in each administrative area representing all branches of medical and ancillary services.

Dr. H. Guy Dain, chairman of the council of the British Medical Association, summed up as follows: "During these last three days we have expressed ourselves in favor of the development of medical services. We have disapproved of the White Paper as it stands. We have preferred the service to proceed by evolution from the present national health insurance, placing first the development of the hospital system and then the extension of general practitioner services. We emphatically do not wish to be employed by local authorities. There should be no civil direction. There should be no whole time salaried service for general practitioners. We will have no clinical control." Dr. Dain asked for final approval of these conditions, and it was unanimously given.

Health of the Nation During the War

In a broadcast address Sir William Jameson, chief medical officer to the Ministry of Health, said that after five years of war he had a good story to tell. The most sensitive index of a nation's general health is probably the proportion of infants dying in their first year, Sir William stated. In the last war, he said, this index rose steadily, but during the past three years it has declined steadily and last year was the lowest on record. In the first month of life a new low death rate record was established, and for the stillborn the rate was only three fourths that of five years ago. The death rates for children up to 10 years of age were also the lowest on record last year, as was the puerperal death rate, it was reported. Finally the birth rate has been rising since 1942 and was now the highest for fifteen years. Factors in this improvement, according to Sir William, were the national milk scheme, vitamin supplements for mothers and young children and the great extension of schemes for school meals and milk in

schools. Full employment and higher purchasing power in many families doubtless also played a part, as well as careful planning of the restricted food supply. We also had the advantage of the system of maternal and child welfare so steadily developed by the local authorities in the twenty years between the two wars. Some of the priorities, such as milk for mothers and children, have been given at the expense of adults. But civilians at all ages were living at least as long as they did in peacetime, and the figures included deaths due to air raids, it was emphasized.

So far we have escaped any serious epidemic during the war. We had an outbreak of influenza in November and December of last year, but it was less severe than the last peacetime epidemic of 1937. Typhoid reached a new low level, and diphtheria was fast coming under control. But there are still the two black spots tuberculosis and venereal diseases. There was an increase in the number of cases of tuberculosis, but the number of deaths from all forms was almost exactly the same as in the last prewar year of 1938, the best year we ever had. Syphilis showed an increase of 139 per cent over 1939. It is encouraging, however, the report stated, that we no longer shut our eyes to this social plague, refuse to discuss it and withhold information about its dangers. This educational program has been welcomed by the vast majority of the public. It has been launched by broadcasting, the press, films, posters and leaflets.

Red Cross Aid to Russia

Speaking at a Red Cross meeting in London, Mrs. Churchill announced that her Aid to Russia Fund now totaled \$30,000,000 and that some 13,000 tons of medical supplies had been shipped. "No convoy which goes on the northern route," she said, "goes without some of our supplies."

American-Belgian Lectures

The bonds of friendship and comradeship between American and Belgian physicians have been more and more strengthened since the arrival of the American Army. On the grounds of this mutual affection and as a result of the proposal of various colleagues (especially Colonels Bachman and Brodtkin of the 15th General Hospital) to organize an international medical body, the International Committee of Military Medicine was recently appointed. The members of the committee resolved to organize medical lectures, to which all the physicians of the region are invited. The first lecture of a series was held on November 3. Colonel Bachman presided. Colonel Voncken, who is general secretary of the International Committee of Military Medicine, congratulated the committee for its organization as well as for having General Reynolds of the Service of Health of the American Army as its president. Topics of the lectures which have been held up to now are "Penicillin in War Surgery," by Colonel Brodtkin; "Therapy of Shock," by Captain Lewy; "Radiotherapy in Basedow's Disease," by Professor Brull, and "Exhaustion of Soldiers After Battle," by Captain Stellar. These lectures are published in the *Bulletin International des Services de Santé des Armées*.

Gastrointestinal Ulcer in Wartime

Some gastroenterologists do not believe in a relation between the conditions created by war and an increase in the development of gastrointestinal ulcers and the aggravation of the symptoms. That this relation seems to exist is indicated by the increased frequency of the disease and the aggravation of symptoms in European countries. Dr. Dauwe in an original article and Dr. N. L. Dumont-Ruyters in an article which was published in *Le Scalpel* arrive at similar conclusions which sup-

port the existence of such a relationship. The sudden increase in the number of cases during the last six months of 1940 excludes the possibility of a progressive increase independent of conditions created by war, they say. One can affirm that these conditions brought about a great frequency in the aggravation of symptoms and an increased number of new cases, it is held. Regardless of the various pathogenic theories about ulcers, it is a fact that several complicated factors play a role when acting on favorable terrain. The authors believe that certain exogenic factors such as smoking and drinking either alcohol or coffee, which in peacetime are considered to be causal factors, are of secondary importance in wartime, during which the mental factors (nervous shock, worry from either material or moral losses) and the influence of these factors on the vagosympathetic balance are the causal factors of main importance.

Gastrointestinal ulcers in peacetime are more frequent in men than in women. However, it is pointed out that in the course of the present war the percentage of gastrointestinal ulcers has increased more in women than in men, probably because of the fact that the former are more nervous than the latter. The increase of working hours and the consequent overstrain may act indirectly on the nervous condition of the people. However, it has been found that the excess of physical work in itself does not exert a preponderant influence on the development of gastrointestinal ulcers, the incidence of which in accordance with the age of the patients has been almost invariable from 1939 to 1942. It is also held possible that hypoalimentation may have an unfavorable local effect on the gastrointestinal mucosa and aid the development of ulcers: the diminution of the number of meals, incomplete diets and the restricted consumption of fats and proteins accelerate evacuation of the stomach. A quicker evacuation of food from the stomach results in a prolonged period of fasting, it is pointed out, during which the gastric mucosa may be injured by hunger contractions on a fasting stomach with hypersecretion. It is also possible that the lowering of nutrition may be an indirect causal factor in ulcer by diminishing the local resistance of gastrointestinal tissues, it is believed.

MOSCOW

Restoration of the Dniepropetrovsk Medical Institute

The Dniepropetrovsk Medical Institute was founded in 1917 on the basis of higher medical education for women and was organized in Ekaterinoslav (now Dniepropetrovsk) in 1916. During the period of socialist reconstruction from 1925 to 1930 the institute was considerably enlarged, apparatus and other equipment were purchased and the general library was organized. The number of students increased from 450 to 1,807 in 1930. Before the outbreak of the present war the institute had 3,275 students. By the twenty-fifth anniversary of its existence the Dniepropetrovsk Medical Institute had given the country 6,448 doctors, 248 teachers, 82 assistant professors and 21 professors.

On Aug. 14, 1941, when the German armies were approaching the city, the institute was moved to Stavropol, but the German offensive in the northern Caucasus in the autumn of 1942 made it impossible to evacuate in organized fashion to the East. Equipment which was not damaged was packed in cases for transportation but had to be left in Stavropol. Many professors, assistant professors, teachers, employees and their families were caught by the Germans and forced to return to the city.

Many members of the staff were soon after shot and killed by the Germans in their "death wagons." Among those who perished were Professors Brikker, oncologist, Brailovsky, psychiatrist, Bezchinskaya, roentgenologist, Shvartsman, therapist

and inventor, Zamkovsky, ophthalmologist, Berg, microbiologist, and some eighty-five other scientific workers and their families.

In far Ferghana in Uzbekistan students, teachers and professors merged with the Fourth Moscow Medical Institute and worked in this fashion until August 1943. After the liberation of the northern Caucasus the basic personnel of the Dniepropetrovsk Medical Institute returned to Stavropol and, after the liberation of Dniepropetrovsk, to their native city, where restoration work was begun. Destruction and damage caused by the invaders were fantastic: the new five story building of the morphologic section lay in ruins, as well as one dormitory and new clinic hospital; buildings of the section on hygiene, the largest dormitory and the administration building were partially wrecked. In the remaining buildings the inner walls had been torn down, and buildings were turned into stables and garages. All furniture and other equipment disappeared. Students and teachers began the work of restoration by clearing away rubble from buildings and making small repairs on the remaining premises. Professors and lecturers found boards and tools and began to manufacture tables and chairs, repair cupboards and carry out other building work. A number of departments were equipped with furnishings brought in the evacuation. The books, which were scattered through the town, were collected in one place and connections were established with various clinics of the city.

The new school year was begun, according to schedule, October 1. At that time some 1,800 students who had applied for the first course had been examined, 600 being accepted by each of three faculties. In addition 7,020 persons who had been students at the institute before the war were enrolled in senior courses. Personnel and students of the institute had to overcome many difficulties. Heads of departments returning from the evacuation found their apartments wrecked and looted and were forced to take up residence with their families in the dormitories, one room being assigned to a family. Under such conditions, deprived of their books and of most essential comforts, five of the scientific workers resumed their activities. Students from other cities were housed at the beginning in dormitories with hardly any glass in the windows and without electric lights. Not all classrooms had been furnished with desks and chairs at the beginning of the school year, and students had to stand during lectures. However, in spite of all these trials and hardships the institute grew considerably between December 1943 and October 1944. The premises are being put in order gradually; the library is being replenished; living conditions are improving; but a great deal of work still remains to be done before the institute can return to its prewar status.

Marriages

WILLIAM L. SHARP to Miss Jean Montgomery, both of Anderson, Ind., at Camp Maxey, Texas, September 2.

JAMES JACKSON HUTSON, Charleston, S. C., to Miss Miriam Poe Hickman of Wilmington, N. C., November 10.

HARRY RICHARD RYAN Jr., Rutland, Vt., to Miss Dansy Paulina Rawls of Dublin, Ga., November 18.

FRANCIS M. BURKE, Coleman, Texas, to Miss Ruth Pettus of Berkeley, Calif., at Dallas, September 15.

CHARLES B. HANNA, Charleston, S. C., to Miss Lena Mae Bryant of Nichols, S. C., September 19.

LYNWOOD EARL WILLIAMS to Miss Dorothy Dean Wells, both of Kinston, N. C., November 25.

CHARLES G. H. MENGES, York, Pa., to Miss Betty G. Cook of Lock Haven, October 7.

WILLIAM N. HORST, Crown Point, Ind., to Miss Jean Mason of Chicago, October 16.

PAUL WILLIAM SPEAR, Baltimore, to Miss Belle Kazan of New York, June 30.

Deaths

M. James Fine * Newark, N. J.; University of Maryland School of Medicine, Baltimore, 1910; member of the American College of Chest Physicians; served during World War I; major, medical reserve corps, U. S. Army, not on active duty; for many years director of the tuberculosis bureau of the Newark Health Department; consulting physician of the tuberculosis division, state health department; examining physician for the National Jewish Hospital, Denver; chief of the tuberculosis service at the City Hospital; tuberculosis consultant for Newark Beth Israel Hospital; on the staff of the Essex Mountain Sanatorium, Verona; consulting and examining physician for the Deborah Sanatorium, Browns Mills; medical consultant to the rehabilitation clinics of the state department of labor; physician to the Essex County Juvenile Court; died December 17, aged 60, of heart disease.

George Monroe Brown Bradshaw * Panama, N. Y.; Columbian University Medical Department, Washington, D. C., 1900; member of the Medical Society of the State of Pennsylvania; served as health officer of the town of Harmony and of the village of Panama since November 1933 and March 1934

War I; member of the Selective Service Appeals Board during World War II; instructor in clinical medicine at his alma mater; on the visiting staffs of the Bethesda General Hospital, St. Luke's Hospital and the Barnes Hospital, where he died November 27, aged 56, of carcinoma of the sigmoid.

Alfred Meyer Goltman * Memphis, Tenn.; Columbia University College of Physicians and Surgeons, New York, 1921; associate professor of medicine at the University of Tennessee College of Medicine; specialist certified by the American Board of Internal Medicine; member of the American Association for the Study of Allergy; fellow of the American College of Physicians; served an internship at the Mount Sinai Hospital in New York; internist to the John Gaston Hospital and the Baptist Memorial Hospital, where he died November 11, aged 49, of coronary heart disease.

Howard Chalfant Adams, Wolbach, Neb.; Rush Medical College, Chicago, 1898; died in St. Francis Hospital, Grand Island, October 30, aged 71, of coronary heart disease, arteriosclerosis and chronic asthma.

Charles Z. Candler * Sylva, N. C.; Atlanta College of Physicians and Surgeons, Atlanta, Ga., 1901; senior fellow of the Southeastern Surgical Congress; life member of the American College of Surgeons; honorary member of the Medi-

Army during World War I; member of the staffs of the Woman's Christian Association and the Jamestown General hospitals; died suddenly November 28, aged 80, of coronary thrombosis.

Frank DeVore Gorham * St. Louis; Washington University School of Medicine, St. Louis, 1912; specialist certified by the American Board of Internal Medicine; member of the American Gastro-Enterological Association; fellow of the American College of Physicians; served overseas during World

War I; member of the State of North Carolina; served during World War I; served as a member of the Dillsboro and Sylva town council; for two years a member of the board of commissioners of Jackson County; founder and chief of staff, C. J. Harris Community Hospital; died December 12, aged 67, of coronary occlusion.

Mallory B. Culpepper * Carlsbad, N. M.; Medical Department of Tulane University of Louisiana, New Orleans, 1894; served as president of the New Mexico Medical Society and the Eddy County Medical Society; bank president and

KILLED IN ACTION

Henry Bertull, Brooklyn; Cornell University Medical College, New York, 1942; served an internship at St. Vincent's Hospital in New York; commissioned a first lieutenant in the medical corps, Army of the United States, on June 10, 1942; later promoted to captain; died in France Aug. 28, 1944, aged 27, of shell fragments in the head and left shoulder received in action.

George William Floss, Swissvale, Pa.; University of Pittsburgh School of Medicine, 1932; member of the American Medical Association; served an internship at St. John's General Hospital in Pittsburgh; commissioned

a first lieutenant in the medical corps, Army of the United States, on Jan. 12, 1943 and began active duty on Feb. 4, 1943; later promoted to captain; drowned in the South Pacific area Oct. 20, 1944, aged 37.

Charles Francis Goetsch, Long Island City, N. Y.; Long Island College of Medicine, Brooklyn, 1936; served an internship at St. Mary's Hospital, Brooklyn; commissioned a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on July 29, 1942; promoted to lieutenant on Oct. 1, 1943; died in the Pacific area July 21, 1944 of a fragment shell wound in the abdomen, aged 33.

member of the school board; on the staffs of the Carlsbad Memorial and St. Francis hospitals; died in St. Mary of the Plains Hospital, Lubbock, Texas, October 13, aged 73, following a prostatectomy.

Rudolph Carl Engel * Cleveland; University of Wooster Medical Department, Cleveland, 1902; medical director of the Republic Steel Corporation; member of the American Association of Industrial Physicians and Surgeons; on the staffs of St. Alexis and St. Luke's hospitals; died in Shaker Heights, Ohio, November 28, aged 65, of coronary thrombosis.

Israel Aaron Fine, Steubenville, Ohio; Ohio State University College of Medicine, Columbus, 1924; member of the American Medical Association; on the staffs of the Gill Memorial and Ohio Valley hospitals; died November 19, aged 44, of coronary thrombosis.

James Irion Hollingsworth, Waurika, Okla. (licensed by years of practice); member of the American Medical Association; councilor of the Fifth District of the Oklahoma State Medical Association; formerly city physician of Muskogee; for eighteen years chief surgeon for the Waurika Hospital, where he died November 30, aged 65, of duodenal ulcer.

Robert Ignatius Hubert, San Marino, Calif.; University of Minnesota College of Medicine and Surgery, Minneapolis,

medical examiner for public schools; served on the staffs of the Harper Hospital, Detroit, and the Borgess Hospital; died November 15, aged 65, of coronary thrombosis.

Jay Richard Lanning * Corinth, Miss.; Memphis (Tenn.) Hospital Medical College, 1900; served in the medical corps of the U. S. Army during World War I; died in the McRae Hospital November 26, aged 72, of coronary disease and diabetes mellitus.

Elmer C. Ludlum, Carmen, Okla.; University Medical College of Kansas City, Mo., 1899; died August 24, aged 69, of coronary thrombosis.

James Roller McMurray * Galveston, Texas; University of Texas School of Medicine, Galveston, 1926; formerly assistant professor of pediatrics at his alma mater; captain, medical reserve corps, U. S. Army, not on active duty; served as physician to the Lasker Home for Homeless Children; on the staff of St. Mary's Infirmary; served an internship and member of the staff of the John Sealy Hospital, where he died October 27, aged 42, of osteomyelitis of the jaw and multiple lung abscesses.

Giles C. Moorehead, Ida Grove, Iowa; State University of Iowa College of Medicine, Iowa City, 1879; member of the American Medical Association; on the staff of the Ida Grove

1898; formerly a member of the city health department of Los Angeles; died November 17, aged 78, of coronary thrombosis.

Frederick M. Ilgenfritz, Kalamazoo, Mich.; Detroit College of Medicine, 1903; member of the American Medical Association;

Hospital; at one time member of the school board; died November 7, aged 88, of chronic myocarditis.

Alexander Cobb Pennington, Steens, Miss.; Chattanooga (Tenn.) Medical College, 1908; died October 1, aged 64.

KILLED IN ACTION

Herman McNeill Lord, Chelsea, Mich.; Wayne University College of Medicine, Detroit, 1938; member of the American Medical Association; served an internship at the Grace Hospital and a residency in obstetrics and gynecology at the Woman's Hospital, Detroit; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on Dec. 4, 1940; began active duty in the Army of the United States on Jan. 27, 1941 and was assigned to the Fitzsimons General Hospital in Denver, where he taught enlisted personnel; promoted to captain; sent to the Mayo Clinic in January 1943 for a course in internal medicine, returning to Fitzsimons for a course in hospital management; after a short period at Northington General Hospital was assigned to the 45th Field Hospital at Fort Bragg, N. C.; sent to England in February 1944; promoted to major; killed in action in Belgium Oct. 27, 1944, aged 33.

John Robert McElroy, Waterloo, Iowa; State University of Iowa College of Medicine, Iowa City, 1941; served an internship at the University of Nebraska Hospital in Omaha; commissioned a first lieutenant in the medical corps, Army of the United States, on June 27, 1941; later promoted to captain; died in the European theater of operations July 28, 1944, aged 28, of wounds received in action.

Bernard Joseph Sabatino, Baltimore; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1938; served an internship and residency at St. Joseph's Hospital; began active duty as a first lieutenant in the medical corps, Army of the United States (National Guard), Feb. 3, 1941; later promoted to captain; field hospital surgeon with the twenty-ninth division; killed in action in the European area, June 6, 1944, aged 31.

Correspondence

RABIES CONTROL

To the Editor:—I read with genuine interest your comment, November 4, concerning rabies in New York City. A program inaugurated in our city of 36,000 inhabitants, just across the border from the city of St. Louis, has yielded excellent results and it might interest other health officers. A number of communities have followed this plan and are pleased with its workings.

Briefly, we shifted the direction of animal control to the health commissioner with gratifying success, yet working in close cooperation with the police department. At one time, one of the film companies was interested but owing to the war, screen portrayal fell through. In addition it was brought to the attention of the United States Public Health Service.

I firmly believe that if the U. S. Public Health Service would sponsor national distribution of a carefully prepared film showing rabid dogs and if the film was carefully edited to bring out the health officers' essential points and emphasizing the reasons for each step, we would get it over to the children attending the picture shows and through them to their parents—the adults. If this portrayal was then followed by a well planned movie showing a puppy who later became rabid—and we have had them—playing with a child or children we would achieve a far reaching result without the necessity of portraying the demise of a child from this horrible disease. This approach would eliminate the alarm to the movie audience, so often composed largely of pregnant women, which the movie industry is anxious to avoid.

Why not clean up rabies once and for all in our nation?

WALTER R. HEWITT, M.D., University City, Mo.
Health Commissioner.

[NOTE.—Following is the plan used in University City:]

The old system wherein the dog catcher travels the streets escorted and guarded by police officers always provoked resistance. We decided to abandon the police escort, since it provoked resistance from the public. We next directed our attention to selecting a certain type of men for the animal control department. The wagon was painted black with "Animal Control" in neat letters on both sides. The men were given an official letter of authority with the University City seal stamped on it. They were dressed in dark blue uniforms and dark visor hats, and around these hats was placed a black hatband on which, in front, "Animal Control" was embossed with 1¼ inch gold letters. The quiet dignity impressed our citizens and enabled us to get away from the old badge idea, which the public likened to police officers and which provoked resistance. Men of kind disposition and smiling countenance were obtained, and they were instructed to present themselves in tailored, clean uniforms, shaven and well groomed. They were further instructed that the public would not understand the law and that they were to be salesmen and emissaries of good will. In approaching people they were to impress on them to keep calm and to talk things over with them. Should the involved party be a woman, they were instructed to raise their hats in approaching her. They were to inform the public that they were paid by the day and not by the number of dogs they caught, that we did not want their pets, that we were anxious to protect their children and their pets, and to ask their help and cooperation.

At once brawls and loud boisterous talk ceased. Less than half a dozen incidents have occurred in the last six months in carrying out this plan. In several instances dogs have been removed from the net by irate citizens, and the animal control men have been instructed to offer no resistance but to obtain the names and addresses of these persons. This matter then comes

under police powers and it is usual for the police to bring the offending party into court on an arrest notice. In this connection it has been found that the payment of costs and a small fine, which may or may not be stayed, on the recommendation of the court works well. It is far wiser than a heavy fine, which is apt to lead to an appeal to a higher court and which creates animosity, which we are attempting to avoid. At the same time a wisely placed appeal for cooperation made from the bench has been helpful and has led to the cooperation of the citizen and has avoided the development of rancor.

Our animal control men are specifically instructed that our ordinance requires all license and impounding fees be paid to our tax collector, and under no circumstances are they to touch any money. Should occasion arise at night, the police department acts for the tax collector.

Guns also are obsolete and should never be permitted. A shooting could easily wreck an entire program. We believe that it is better to allow the dog to be taken away or to escape, as by that very act one makes friends among the citizenry. It will save broken noses or litigation, and it places the burden on the citizen.

When we instituted this program, "mercy acts" were permitted and dogs were released on the citizen's signature on recommendation of our animal control department when there was justifiable reason. These little acts further ingratiated the department in the minds of the public. The citizen invariably responded by expressing appreciation and offering to cooperate with the department.

Remember, animal control is on a higher plane than dog catching and is designed to protect each of us as well as our pets from the stray that is a reservoir for rabid dogs. We believe that citizens and their pets should be treated kindly, courteously and sympathetically. This simple method has led almost to tripling the number of licenses issued. Only an occasional dog is now seen on the street at large. The number of dog bites is decreasing.

Bureau of Investigation

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE.—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated D.D.N.J. and foods, F.N.J. The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the date of shipment; (4) the composition; (5) the type of nostrum; (6) the reason for the charge of misbranding, and (7) the date of issuance of the Notice of Judgment.]

Bafaline Tablets.—Bafaline Laboratories, Inc., Manchester, N. H. Shipped Jan. 7 and July 18, 1941. Composition: essentially acetylsalicylic acid and caffeine, with indications of gelsemium. One consignment was declared misbranded in that the label statements represented that the product would be effective in relieving pain, colds and discomfort resulting from various rheumatic pains, act as a restorative on the nervous system, and accomplish some other things.—[D.D.N.J., F.D.C. 828; December 1943.]

Brown's Nosopen.—Am-Bro Company, Lawton, Okla. Shipped Jan. 7, 1942. In two units, "No. 1 Solution" and "No. 2 Solution." Composition: No. 1 essentially ephedrine sulfate (about 1 per cent), chlorobutanol and water; No. 2, essentially ephedrine alkaloid (approximately ¼ per cent) and small amounts of volatile oils, including camphor, menthol and eucalyptus in a mineral oil base. Both bottles misbranded because they contained ephedrine but labels failed to warn that frequent or continued use might cause nervousness, restlessness and sleeplessness, and that preparations should not be taken, except on competent advice, by persons suffering from high blood pressure, heart disease, diabetes or thyroid trouble, and because the No. 2 Solution contained mineral oil, whereas its label failed to warn that frequent or excessive use might injure the lungs, and that the product should not be given to infants

and young children except on competent advice. Further misbranded because name "Nosopen" falsely suggested that preparation would open nasal passages and make breathing easier. Also misbranded because use of the words "Discomforts of Hay Fever, Asthma, Sinus Head Colds" was false and misleading in representing that Nosopen would be efficacious for all discomforts of the conditions named, whereas it would be effective only to lessen nasal congestion.—[D.D.N.J., F.D.C. 811; December 1943.]

Clearwater's Combination Medicine.—Henry P. Clearwater, trading as Pope Laboratories, Hallowell, Maine. Shipped July 18 and August 12, 1940. Three products in combination. Composition. No. 1, a pink tablet, essentially a mixture of ferrous carbonate, potassium iodide, calcium glycerophosphate, manganese dioxide, sulfur, and a compound of zinc; No. 2, a white tablet containing cascara, and No. 3, a pink compressed tablet consisting largely of aspirin and starch. Misbranded because falsely represented to be efficacious as a reconstructive systemic tonic and a treatment and preventive of rheumatism and arthritis.—[D.D.N.J., F.D.C. 822; December 1943.]

Ecco Hygienic Powder.—Eby Chemical Company, Harrisburg, Pa. Shipped April 13, 1942. Composition. Essentially boric acid and alum, with small amounts of oxyquinoline sulfate, menthol, thymol, phenol, eucalyptol, salicylic acid and methyl salicylate. Bacteriologic tests showed that it was not germicidal in the dilution recommended for use. Misbranded because labeling falsely represented that it was a reliable contraceptive and appropriate treatment for head colds, rhinitis, rectal irritations, bleeding gums, trench mouth, abscesses, boils, hemorrhoids, leucorrhea, vaginitis, gonorrhea and many other disorders.—[D.D.N.J., F.D.C. 830; December 1943.]

Heilmann's Formula "99."—Frank J. Heilmann, trading as Heilmann's National Distributors, Los Angeles. Shipped August 7, 1941. Composition: essentially potassium acetate, potassium iodide, resinous matter, colchicin, alcohol and water. Misbranded because labels falsely represented that the product would act as a stimulant diuretic, benefit gouty conditions, prevent heart injury resulting from the pain, discomfort and ill effects of gouty and rheumatic conditions; would be of value in preventing many forms of rheumatism, as well as syphilitic neuralgia; prevent and immediately relieve pain, produce buoyant energy and accomplish some other things.—[D.D.N.J., F.D.C. 826, December 1943.]

Ironized Yeast.—Ironized Yeast Company, Inc., Atlanta, Ga. Shipped prior to Dec 20, 1941. Composition not reported, except quotation from label: "Each tablet contains reduced iron—Iron Peptonized Haemoglobin Vitamin B Concentrate from Yeast Lager Yeast." Misbranded because labeling falsely represented that the product would be beneficial for underweight, run-down, tired and nervous people, would increase weight, vigor and appetite and dispel weariness.—[D.D.N.J., F.D.C. 838; December 1943.]

Neo-Sed.—Hale Drug Company, Birmingham, Ala. Shipped Jan. 7, 1942. Composition: essentially barbital (0.7 grain per fluid ounce), compounds of sodium, ammonium and potassium, bromides, benzoic acid, sugar and water. Misbranded because label did not adequately warn that frequent or continued use of product might lead to mental derangement, skin eruptions or other serious disorders, and that it should not be taken by those suffering from kidney diseases. Also misbranded because fabricated from two or more ingredients, whereas label failed to state common or usual names of these or to declare quantity of bromide present. Further misbranded because label did not accurately state the amount of contents.—[D.D.N.J., F.D.C. 809; December 1943.]

Old Hickory Ointment.—Old Hickory Medicine Company, Chattanooga, Tenn. Shipped May 5, 1942. Composition: essentially a mixture of zinc oxide, salicylic acid, calomel, carbolic acid, camphor, menthol and petrolatum. Misbranded because label falsely represented the product as being effective in the treatment of acne, barber's itch, tetter, dandruff, psoriasis, itching piles and some other things. Further misbranded because label failed to state the quantity or proportion of calomel, a mercury derivative, that was present.—[D.D.N.J., F.D.C. 839, December 1943.]

Pine Glow Bath and Rainbo Bath.—Rainbath Laboratories, San Francisco. Shipped Feb. 16, 1942. Composition. Pine Glow Bath, essentially water, with the sodium salt of a sulfonated oil, and volatile oils, including oil of pine needles; Rainbo Bath was essentially a lime-sulfur solution. First product misbranded because falsely represented in labeling as effective in overcoming insomnia, aiding health and benefiting muscular rheumatism and gout and eliminating poisons, increasing the white corpuscles and bringing about weight reduction. Rainbo Bath misbranded because of false label representations that the product was colloidal sulfur and that when placed in the bath water would give the benefits derived from the treatments at hot springs and spas.—[D.D.N.J., F.D.C. 836, December 1943.]

Purola Female Pills.—McKesson & Robbins, Inc., and Blumauer-Trank Drug Company, Portland, Ore. Shipped Nov. 19, 1941. Composition: essentially laxative plant drugs, including aloes, with oil of tansy, alkaloidal material (probably derived from ergot) and iron sulfate. Misbranded because, in spite of laxative ingredients, the label did not warn that the product should not be used when abdominal pain, nausea, vomiting, or other symptoms of appendicitis are present, and that frequent or continued use might result in dependence on a laxative; further misbranded in that name "Female Pills" and directions inside box to take pills prior to "expected period" gave the false and misleading impression that the preparation would be effective in promoting the menstrual flow, whereas it would not.—[D.D.N.J., F.D.C. 813, December 1943.]

MEDICOLEGAL ABSTRACTS

Right of Discharged Army Medical Officer to Employment Held Prior to Entering Service.—Kay "entered the service" of the General Cable Corporation in July 1931 as the "medical director" of one of its plants on the basis of a "full working week" at the plant. About six months later "this was reduced to three hours a day" five days a week, although he remained "on call" by the corporation at all hours and was expected as needed to visit at their homes or at a hospital employees injured in the course of their employment. His duties were to render all necessary medical care to employees so injured, to make preemployment physical examinations and to conduct routine physical examinations of all employees. The corporation furnished him at its plant fully equipped a waiting room, dispensary, treatment room, rest room, drug room and two examination rooms. Four nurses employed by the corporation assisted him and he had no right either to hire or to discharge the nurses. He was paid a certain sum weekly without regard to the number of patients he treated or the number of hours he spent in treating employees of the corporation. From this weekly compensation the corporation "deducted payments for social security and unemployment compensation." At one time when Kay's draft board classified him as 1-A the corporation filed an affidavit for his deferment, describing him as "a regular employee." Outside the plant he maintained his own office, where he received his private patients but where also he was required to receive such employees as were sent by the company.

Kay entered the Army, served six months and was honorably discharged. The corporation refused to reinstate him in his former capacity and he brought action against it to compel his reinstatement under section 8(e) of the Selective Training and Service Act of 1940, which provides that any person who, on entering the military or naval service of the United States, has left "a position, other than a temporary position, in the employ of any employer" shall, in the case of a private employer, be restored to such position or to a position of like seniority status and pay, "unless the employer's circumstances have so changed as to make it impossible or unreasonable to do so." The trial court dismissed his action on the ground that he did not hold a position "in the employ" of the corporation, and Kay appealed to the circuit court of appeals, third circuit.

The status, said the circuit court of appeals, protected by the Selective Training and Service Act is "a position . . . in the employ of" an employer—an expression evidently chosen with care. It will be noted that the word "employee" was not used in the statute. While it may be assumed that the expression which was adopted is roughly synonymous with "employee," it unmistakably includes employees in superior positions and those whose services involve special skills, as well as ordinary laborers and mechanics. Of course, the words are not applicable to independent contractors, but, except for casual or temporary workers, who are expressly excluded, they cover almost every other kind of relationship in which one person renders regular and continuing service to another. The policy of the act is stated in section 1(b), 50 U. S. C. A. Appendix, section 301(b), to be that "the obligations and privileges of military training and service should be shared generally in accordance with a fair and just system . . ." though such declaration was hardly needed. Every consideration of fairness and justice makes it imperative that the statute should be construed as liberally as possible so that military service entail no greater setback in the private pursuit or career of the returning soldier than is unavoidable. The question here presented, therefore, is not to be solved by the application of abstract tests or formulas, but the factors which usually determine the nature of a disputed relationship must be considered in the light of the purpose which Congress intended to accomplish. Of course, the corporation could not exercise any control over the details of Kay's work

as a physician. The method of physical examination, the diagnosis and the treatment of injuries were necessarily his sole province, and if the right to dictate the manner of doing the work were the final and decisive test Kay could not be classed as an employee. However, even in cases in which the interpretation of a statute is not involved, that is by no means the only thing to be considered. In the present case the manner in which Kay was paid, the extent to which his time was at the corporation's disposal and the right of the company to discharge him at any time point to an employee status rather than that of an independent contractor. So long as he was associated with the corporation he did not have the practicing physician's freedom to choose his own patients but was bound to receive and treat every case referred to him by it. Ownership of the premises on which Kay did most of his work and of the instrumentalities used, as well as the control of his subordinates and assistants, were all in the corporation. For what it is worth, the defendant unquestionably considered him no different from any ordinary employee. It required him to punch a time clock and rewarded him with the employee's regular ten year service button, the Army and Navy E certificates and employee's bonus for enlistment. The relationship which resulted from all these various factors, viewed in the light of the purpose of the statute, is clearly a position in the employ of the corporation and is perhaps better described by that term than any other which could be found.

We agree, continued the court, with the learned judge of the district court that the circumstances of the employer did not, during the plaintiff's absence, change so as to make it unreasonable for the corporation to reengage him. The change in circumstances on which it grounded its refusal was this. In addition to his position with the corporation, the plaintiff had been engaged as physician for an employees' health association, each member of which paid a monthly premium. Kay received a certain fee per month for each member, for which he was to give the members medical treatment for ills not connected with compensable injuries, which were the subject matter of his employment with the corporation. When Kay went into the Army the health association employed another physician. On his return the association declined to reemploy him preferring the new man. The position of the corporation is that it makes for greater efficiency and avoids some loss of the workers' time to have the same physician for both the company and the health association. There is also a faint suggestion that Kay had for some reason become unacceptable to the health association, but there is no evidence whatever of a change in his personal relations with the corporation and it is not suggested that his professional qualifications, his mental or physical ability to do the work or his personal characteristics had altered in any way, or that the corporation had any reason to believe that his services as medical director would be in any way different or less satisfactory than they were before he left. The Selective Training and Service Act says, unless the "employer's" circumstances have changed. Primarily, no doubt, this was intended to provide for cases in which necessary reduction of an employer's operating force or discontinuance of some particular department or activity would mean simply creating a useless job in order to reemploy the veteran. Without deciding whether a change in the veteran's relations with other employees or with third parties generally can ever constitute a change in the "employer's" circumstances within the meaning of the act, and assuming that the refusal of the association to reemploy him is a relevant fact, we believe that there was no change in this case which would make it unreasonable for the corporation to reengage Kay. Accepting the corporation's contention that there would be some loss of efficiency and possibly some additional expense involved, more than that is needed to justify refusal to reinstate a person within the protection of the act. In most cases it is possible to give some reason for the refusal. "Unreasonable" means more than inconvenient or undesirable. The company's argument on this point, if carried to its necessary conclusion, would defeat the main purpose of the act and limit its operation to merely capricious or arbitrary refusals. Men and women returning from military service find themselves, in countless cases, in competition for jobs with persons who have been filling them in their absence. Handicapped, as they are bound to be by prolonged absence, such competition is not part of a fair and just

system, and the intention was to eliminate it as far as reasonably possible. The act intends that the employee should be restored to his position even though he has been temporarily replaced by a substitute who has been able, either by greater efficiency or by a more acceptable personality, to make it desirable for the employer to make the change a permanent one.

The court accordingly remanded the cause to the district court with instructions to enter a judgment that in effect would compel Kay's reinstatement to the position he held with the corporation prior to his entry into the Army.—*Kay v. General Cable Corporation*, 144 F (2d) 653 (1944)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Influence of Sulfonamides on Postoperative Complications.—Rhoads and Ravdin studied the mortality of the postoperative infection occurring in a general surgical service and made a comparison of the experience during the three years prior to the introduction of the sulfonamides with the experience during the four years following their general acceptance. The most important advance occurred in the treatment of postoperative bronchopneumonia, the gross mortality dropping from 69 per cent to 9 per cent. It is pointed out that better control of postoperative complications not only permits some saving of life but also permits a broader selection of patients, especially in the older age groups, for certain operations which are indicated but in which in the past the contraindications have slightly outweighed the indications.

Partial Pericardiectomy and Epicardiolysis in Constrictive Pericarditis.—Harrington reports 24 cases in which partial pericardiectomy and epicardiectomy with epicardiolysis were performed. He uses the term "epicardiolysis" to designate the separation of the innermost layer of the pericardium from the heart muscle. This procedure is used in addition to resecting a portion of pericardium and epicardium. Epicardiolysis is an important and essential part of the operative procedure. Immediately after operation all patients are placed in an oxygen tent. The oxygen not only prevents cyanosis but aids in relieving stress on the heart. Other postoperative measures are directed toward removal of body fluids and aiding the function of the heart and liver. In 9 cases of chronic constrictive pericarditis cure resulted from pericardiectomy; in another 9 cases the operation was followed by improvement, whereas death followed in the remaining 6 cases. This amounts to a mortality rate of 25 per cent. Although this is relatively high, the author thinks that this is commensurate with the seriousness of the disease and that the mortality rate would have been 100 per cent without surgical intervention. Eleven of the 24 patients can be considered cured at this time, and 2 additional patients may subsequently improve.

Relationship of Protein Deficiency to Surgical Infection.—Cannon and his associates demonstrated by both immunologic and chemical methods that in the blood serums of protein deficient rats there is a lowered concentration of antibody globulin fractions. This indicates the adverse action of protein deficiency on protein reserves. In many surgical conditions serum protein fractions are lost through exudates, hemorrhage or the kidneys. Furthermore, undernutrition caused by an inadequate intake, absorption or utilization of high quality protein may lead to depletion of the tissue protein reserves both before and after operation. This loss of tissue proteins may become critical if and when a potentially pathogenic microorganism enters tissues unprepared to mobilize the forces of acquired resistance. Reliance on the so-called albumin-globulin ratio for the determination of the state of the tissue protein reserves is inadequate. We need to know not only whether the globulins are in a lowered concentration but particularly whether there is a diminished concentration of the gamma globulin fraction. In the absence of a quantitative clinical method for determining the concentration of gamma globulin, dependence must be placed on the evaluation of the preoperative weight loss and total serum protein determinations. If the total serum protein concentration is found to be less than 5 Gm. per hundred cubic centimeters of serum, preoperative protein repletion should be attempted. Gamma globulin presumably contains many if not most of the essential amino acids. For its synthesis it is necessary to provide an abundance of essential amino acids. In patients with depleted globulin reserves repletion necessitates the ingestion or intravenous administration of proteins containing all of the essential amino acids. The further effects will depend on the patient's ability to convert these amino acids into tissue proteins, including antibodies.

Closure of Colonic Stoma.—Dixon and Benson report 102 consecutive cases in which succinylsulfathiazole and sulfathiazole were employed while the patients were hospitalized for closure of colonic stomas. In order to obtain an unbiased evaluation of the results of this treatment, three other groups of cases have been considered. Group 2 included 102 consecutive cases in which no sulfonamide drug was used. Group 3 included 40 cases in which only sulfanilamide was employed. Group 4 embraced 30 cases in which only sulfathiazole was administered. The authors stress that the oral administration of succinylsulfathiazole and the local application of sulfathiazole to the operative wound have greatly improved the results obtained in closure of colonic stomas. Infection of the operative wounds occurred in 84 per cent and a fecal fistula developed in 30 per cent of a series of 102 cases in which no sulfonamide drug was employed, whereas infection of the wounds occurred in only 13 per cent and a fecal fistula occurred in only 2 per cent of 102 cases in which a combination of succinylsulfathiazole and sulfathiazole was administered. These improvements are in large part attributable to the new chemotherapeutic agent succinylsulfathiazole, and they indicate the usefulness of this drug in surgical diseases of the lower intestinal tract.

Electroencephalogram in Alcoholism.—Greenblatt and his associates studied the electroencephalograms and clinical histories of 157 patients with chronic alcoholism with and without psychosis, including patients with convulsions due to chronic alcoholism. They found that the incidence of electroencephalographic abnormality in patients with chronic alcoholic disorders increases with age. Persons with chronic alcoholism without psychosis, irrespective of the duration of drinking, show nothing of significance in the electroencephalogram. Chronic alcoholism with psychosis is associated with a higher than normal incidence of electroencephalographic abnormality. The presence of confusion or hallucinations in patients with alcoholic psychosis is frequently associated with electroencephalographic abnormality, and the disappearance of hallucinations or confusion is often accompanied by a change toward a more normal electroencephalogram. No evidence of paroxysmal dysrhythmia was found in 5 patients with pathologic intoxication, although 3 of the 5 patients had abnormal electroencephalograms. The highest incidence of electroencephalographic abnormality was found among those with deterioration or Korsakoff's syndrome. No specific electroencephalographic pattern was found in 4 patients with Korsakoff's psychosis. A relatively low incidence of electroencephalographic abnormality was found in 24 patients with "rum fits" (with a negative history for epilepsy and with seizures occurring only in association with alcoholism). On the other hand, a relatively high incidence of electroencephalographic abnormality was found in patients with idiopathic epilepsy with onset of seizures in the same age range as that of the patients with "rum fits." The authors conclude that an abnormal electroencephalogram may be of aid in predicting the duration of illness in patients hospitalized for chronic alcoholism.

Reduced Atmospheric Pressure for Sinusitis.—In the past two years Butler and his associates used the decompression method for 125 patients with subacute and chronic sinusitis. All the patients had symptoms attributable to sinusitis and the majority had been referred to the authors after measures such as surgical treatment, lavage, siphonage, vaccine injections and diathermy had failed. No patients with acute sinusitis have been included in the series. The average duration of the sinus disease in the patients studied was 9.5 years. Treatments were administered in a large decompression chamber of the type currently used for studies of aviation medicine. The pressure was rapidly reduced to 522.6 mm. of mercury, the equivalent of ascent to an altitude of 10,000 feet. The rate of the "ascent" was 5,000 feet per minute. On reaching the pressure at 10,000 feet recompression ("descent") was begun, but at the much slower rate

of approximately 700 feet per minute. Rapid "ascent" to 10,000 feet was alternated with slow "descent" to 5,000 to 6,000 feet for a period of forty minutes, and then slow "descent" to ground level completed the treatment. Patients were treated twice a week. Altogether, 2,259 treatments were given to the group—an average of 18.1 treatments per patient. At the conclusion of their course of treatment 89.5 per cent of the 125 patients experienced subjective improvement. Of 29 patients who were followed by serial x-ray studies after instillation of radiopaque oils, 17 showed improvement in the roentgenogram after the decompression treatments. Of 42 patients who were studied by repeated rhinologic examinations, 30 showed improvement in their sinus condition after being treated by decompression.

Plasmochin Intoxication.—West and Henderson report observations on 846 cases of malaria caused by *Plasmodium falciparum*. All patients were hospitalized. Therapy consisted of 10 grains (0.65 Gm.) of quinine sulfate three times daily after meals for three days, or until the temperature was controlled, followed by atabrine 1½ grains (0.1 Gm.) three times daily after meals for five days. Complete blood cytologic examination of each patient was done at the completion of eight days of therapy, and no patient was discharged from the hospital until three consecutive negative smears had been reported and the erythrocyte count was above 4 million. After a rest period of two days each patient was placed on plasmochin 0.01 Gm. three times daily after meals for five days. All of the 846 patients with malarial fever received plasmochin treatment and 24 were readmitted to the hospital suffering from complaints which were believed to have resulted from plasmochin intoxication. Of these 24 patients, 2 had experienced four previous attacks of malarial fever each. Plasmochin had been administered to these 2 patients after each previous attack without untoward reactions. The remaining 22 patients had not previously been infected with malaria. The sign-symptom complex presented by these patients was not duplicated by patients not having received plasmochin. The complex consisted of jaundice, abdominal pains, headache, nausea and vomiting. Other symptoms were hyperexcitability, both subjective and objective, dizziness, stiffness and pains in the joints, low back pains and eructations of gas. Therapy was supportive and expectant. Forced fluids, including reconstituted plasma and isotonic solution of sodium chloride with 5 per cent glucose, were administered in the severe cases by venoclysis, and alkalization was a routine measure. All patients recovered. Previous history of yellow fever inoculations in all of the patients suggests the possibility of such inoculations having had some influence on the incidence of plasmochin intoxication. The authors arrive at the following conclusions: 1. Plasmochin is potentially a highly toxic drug when administered in large doses. 2. Plasmochin may produce varying degrees of secondary anemia. 3. There is no relationship between the number of previous attacks of malaria, the parasitic index and the incidence of plasmochin intoxication. 4. The individual reaction to plasmochin is inconstant and unpredictable. 5. The untoward results of plasmochin are not permanent, but convalescence is protracted. 6. The dosage of 0.01 Gm. of plasmochin twice daily for two days is sufficient in most instances to render the blood of a malarial patient noninfectious for mosquitoes and is simultaneously a safe dosage from the standpoint of potential toxicity.

Vitamin B and Liver in Celiac Disease.—Certain aspects of the disease, according to Paterson and his co-workers, suggest that it may be a deficiency syndrome and that the vitamin B complex may be involved. The similarity of certain symptoms to those encountered in nontropical sprue and in the chronic vitamin B deficiency syndrome of adults seems significant. Celiac disease appears to be six or seven times more prevalent in the British Isles since the outbreak of war in September 1939. Because of the problems related to the dietary treatment of celiac disease under wartime conditions, the views of May et al. attracted much attention. They advocated a normal, balanced diet, supplemented by vitamins A, C and D, combined with the parenteral administration of crude liver and vitamin B complex. Twenty-six patients with idiopathic celiac disease and 4 patients with the celiac syndrome were treated by Paterson and his co-workers with liver extract given parenterally and vitamin B complex given parenterally and orally. Satisfactory gains in weight and height, and improvement in general health were obtained in the early weeks of treatment and sustained over a period of months in the patients who received sufficiently intensive and prolonged therapy. Less dramatic improvement and less satisfactory weight gains resulted when the parenteral liver extract was given in conjunction with an oral instead of a parenteral vitamin B complex preparation. The children thrived on a normal balanced diet during or after the initial weeks of treatment. The total stool fats improved in all but 4 cases and returned to normal in 18 of 26. Slow improvement was commonly associated with the occurrence of upper respiratory infections. In the secondary type of the disease the "celiac syndrome," resulting from chronic foci of infection, improvement appeared to be hastened by intensive therapy with liver and vitamin B complex.

Desert Climate.—Ladell and his collaborators outline observations made in southern Iraq on British army personnel. Physiologic and biochemical observations were made each week from May to October on 24 soldiers. These were to serve as controls for similar observations made on men suffering with

the effects of heat. All of the fit men lost some weight. The loss was greatest in those who had the highest chloride concentrations in their sweat. It is suggested that this loss was due to a minor degree of salt deficiency dehydration. Salt deficiency dehydration was indicated by low urine output in spite of a high water intake, low urinary chloride output and raised blood urea. The blood pressure fell as the weather grew hotter. Twelve cases of hyperpyrexia are described. The onset was acute, with absence of sweating and loss of consciousness. These patients all went through a phase of apparent negative water balance; they excreted large quantities of dilute urine at a time when they were drinking little. During this phase the chloride content of the blood was diminished. These findings support the view that hyperpyrexia is accompanied by superhydration. Two distinct types of heat exhaustion were observed. Patients with type 1 heat exhaustion were seen mainly in the first half of the summer. Vomiting and cramps were common. The patients were pale, collapsed and sweating profusely. The blood pressure was occasionally low, but the most consistent abnormality was reduction in pulse pressure; on standing, syncope occurred. Heat exhaustion type 1 was a salt deficiency dehydration; plasma and whole blood chlorides were grossly diminished, hemoglobin and plasma protein were raised, blood urea was high, extracellular fluid and plasma volumes were diminished, and the urine was scanty, of high specific gravity and almost free from chloride. Treatment of these patients consisted in replacement of salt and water. There is evidence that type 1 heat exhaustion occurs in persons who habitually secrete sweat containing a much higher concentration of chloride than the average; their salt intake is inadequate at high rates of sweating, and they become salt deficient. Prevention of these cases might be achieved by increasing the salt intake. Any man who is consistently losing weight and is excreting a concentrated urine with low or absent chloride should be given extra salt. Cases of heat exhaustion type 2 were seen only in the second half of the summer among men who had already come through the hottest weather unscathed. Clinically they were characterized by defective sweating and polyuria; the skin showed prickly heat in the healing and desquamating stage. These patients were salt deficient, but not so grossly as those of type 1, and they were not dehydrated. During convalescence they secreted a sweat with a high concentration of chloride. Signs of a similar breakdown were found in some of the fit men in that during the second half of the summer their sweat was richer in chloride than it had been during the first half. The incidence of heat exhaustion type 2 could probably be reduced if men—particularly those suffering from severe prickly heat—were given a break of a few days in a cooler climate after eight weeks' continuous exposure to extreme desert conditions.

Treatment of Staphylococcal Infections with Penicillin.—Bigger says that results obtained by him strongly oppose the commonly accepted belief that penicillin is merely bacteriostatic. He cites observations which justify the statement that penicillin is bactericidal for *Staphylococcus pyogenes*. The author further shows that failure of penicillin to sterilize broth containing *Staphylococcus pyogenes* is due to the survival of a small number of staphylococci called persisters. It is believed that persisters are insensitive to penicillin because they are temporarily in a nondividing phase and because penicillin kills only bacteria which are about to divide. Unlike resistant strains, descendants of persisters are easily killed by penicillin. Penicillin fails to cure staphylococcal infections in the body because some of the cocci are in the persister phase. A scheme of treatment in which penicillin is alternately administered and withheld is suggested in the hope that bacteria in the persister phase will divide during an intermission and be killed by penicillin when its administration is recommenced. The details of treatment must depend on clinical trials, but it is suggested that the first treatment should extend to four days and subsequent treatments to two days. It is difficult to decide on the optimum duration of intermissions. If too short, only a few persisters may have resumed their activities. If too long, a fresh infection may have begun. A tentative scheme suggested by the author provides that the first two intermissions should last one day each, the other two, however, two and three days respectively.

Book Notices

Manual of Military Neuropsychiatry. Edited by Harry C. Solomon, M.D., Professor of Psychiatry, Harvard Medical School, Boston, and Paul I. Yakovlev, M.D., Clinical Director, Walter E. Fernald State School, Waltham, Mass. With the collaboration of Wilfred Bloomberg, Lt. Col., M. C., A. U. S., et al. Cloth. Price, \$6. Pp. 764, with illustrations. Philadelphia & London: W. B. Saunders Company, 1944.

Essays from forty-five contributors dealing with the various aspects of military neuropsychiatry have been assembled by the editors into a compact and attractive volume which is intended for use principally by medical officers of the armed forces stationed where adequate reference material may not be available. The contents are divided into (1) introduction, (2) induction, (3) administration and disposition, (4) clinical entities, (5) prophylaxis and therapy and (6) special topics. The reported organization of the neuropsychiatric examination at the induction station is based chiefly on experiences of the authors at the Boston Induction Station. The differences in the administration and disposition of the neuropsychiatric cases in the Army, Navy and Merchant Marine are well presented. Description and discussion of the common clinical neurologic and psychiatric entities are given in clear concise language in part 4. This section is somewhat weakened by a lack of presentation of clinical entities which seem peculiar to the different military groups during or following combat. The editors comment that most of these clinical entities are essentially the same, whether they occur in a soldier or in a civilian. Many other authorities in the field would not agree to such an opinion, and a good deal of factual information has been collected to show that there are often gross differences in the types of mental illness commonly seen in the soldier and in the civilian. Prophylaxis and therapy are adequately presented and include an excellent discussion of the will to fight. Special topics presented in part 6 include the neuropsychiatric aspects of tropical diseases, disorders incident to the tropics, hazards of flying, convoy and torpedo casualties, experiences of foreign armies and a clinical discussion of cerebrospinal fluid and electroencephalography.

Orthopedic Surgery. By Walter Mercer, M.B., Ch.B., F.R.C.S., Assistant Surgeon, Royal Infirmary, Edinburgh. With a foreword by Sir John Fraser, Bart., K.C.V.O., M.D., Regius Professor of Clinical Surgery in the University of Edinburgh. Third edition. Cloth. Price, \$12. Pp. 947, with 415 illustrations. Baltimore: William Wood & Company, 1943.

To those who have read the first edition of this treatise the appearance of a third will serve as additional proof of its popularity. Important additions have been made in the chapters on circulatory disturbances, disorders of the back, knee, shoulder and foot, and infections of the hand. These additions have helped to bring the book up to date.

One cannot but help being impressed, as one reads, with the scope and importance of modern orthopedic surgery. Mercer has included not only diseases of the bones, muscles and tendons but also those of the nerves and blood vessels. In other words, orthopedic surgery now includes practically all extremity surgery and, in addition, many important diseases of the trunk. To cover all of these subjects adequately in a volume of 900 pages is an almost impossible task. Dr. Mercer has done an excellent piece of work, considering the inherent difficulties which he faced.

It must be constantly borne in mind that only an outline can be given and that for the successful practice of orthopedic surgery the details of the picture must be filled in by a thorough knowledge of the compendious current literature. Were the author to attempt to include a discussion of the numerous divergent views regarding diagnosis and therapy, the volume would become so bulky as to make publication almost impossible. Brevity must therefore replace the details of the highly specialized studies dealing with single phases of orthopedic surgery. This essential limitation of the book makes itself particularly evident in such chapters as the one on bone tumors, where the diagnosis rests on accurate knowledge of numerous details. In other chapters, such as the one on tuberculosis, this difficulty does not make itself as keenly felt.

For the general practitioner, as well as for the general surgeon, this book is of particular value.

A Concise Pharmacology and Therapeutics of the More Important Drugs, Together with an Introduction to the Art of Prescribing. By F. G. Hobart, Ph.C., Head of the Pharmaceutical Department, Westminster Hospital, London, and G. Melfon, M.D., M.R.C.P., Senior Physician, Dudley Road Hospital, Birmingham. With a foreword by Sir Adolphe Abrahams, O.B.E., M.A., M.D. Second edition. Cloth. Price, 12s. 6d. Pp. 168. London: Leonard Hill, Ltd., 1944.

According to the authors, this book is intended "only to discuss the action of drugs in relation to practical therapeutic considerations" and "represents an attempt to present concisely, but in sufficient detail, the pharmacology of the more important drugs used in the British Commonwealth and the United States of America." Unfortunately, the authors have made such a concise presentation that the value of the book is lessened. It is not suitable for medical students unless supplemented by the better known textbooks on pharmacology and therapeutics. Errors are occasionally seen. For example, the authors state that mild silver protein is a preparation similar in character to strong silver protein but it contains a considerably smaller proportion of silver. Apparently it has been forgotten that the adjectives "strong" and "mild" refer to the therapeutic action, as made evident by the degree of ionization, and not to the total silver content. Also there are not included a few of the more well known new drugs. For instance, in the sulfonamide section, sulfamerazine and sulfapyrazine are not included.

For those who like to maintain complete libraries the book may provide some additional value, as it supplies a list of proprietary names and nonproprietary equivalents presumably in England. The number of names in this list is almost three hundred.

Practical Occupational Therapy for the Mentally and Nervously Ill. By Louis J. Haas, F.A.A., O.T.R., Director, Men's Therapeutic Occupations, The New York Hospital, Westchester Division, White Plains, N. Y. Cloth. Price, \$6. Pp. 432, with 356 illustrations. Milwaukee: Bruce Publishing Company, 1944.

This edition is evidently arranged primarily for the occupational therapy worker in mental hospitals. Over half the book is devoted to technics of various crafts; another portion is devoted to the operation of the occupational therapy department, while a smaller part is used for the excellent portrayal of history and theory of occupational therapy as applied to mental patients. Although it is not suitable as a textbook in schools of occupational therapy, the book will serve as a source of inspiration for the many therapists in mental hospitals. Physicians and administrators will find this volume helpful in gaining a working knowledge of occupational therapy and its uses in treating mental patients. Commendable features are the bibliographies at the end of the chapters and the use of case history reports to demonstrate principles. These features clarify the theory and emphasize the practical applications of occupational therapy.

Manual of Human Protozoa with Special Reference to Their Detection and Identification. By Richard R. Kudo, D.Sc., Associate Professor of Zoology, The University of Illinois, Urbana. Cloth. Price, \$2. Pp. 127, with 29 illustrations. Springfield, Ill. & Baltimore: Charles C Thomas, 1944.

This manual is made up from the laboratory notes of an emergency course given at the University of Illinois. It contains brief descriptions and diagnostic figures of the Protozoa found in the digestive tract, circulatory system and tissues of man. Technics for their preparation for microscopic examinations are also given. Keys for the differential diagnosis of the intestinal amebas and flagellates are provided. The illustrations are excellent but too limited for critical work on the life cycles of some species. It is a convenient handbook for use in the clinical laboratory.

Studies on Immunisation, Second Series with Appendices Dealing with Anti-Typhoid Inoculation, Chemo-Therapy and Statistical and Other Operations of Induction. By Sir Almroth E. Wright, M.D., F.R.S., Director of the Inoculation Department and Principal of the Institute of Pathology and Research, St. Mary's Hospital, London. [Reprints.] [Researches from the Inoculation Department, St. Mary's Hospital, IV.] Cloth. Price, 25s. Pp. 256, with illustrations. London: William Heinemann, Ltd., 1944.

This is another volume of "collected researches" from the inoculation department of St. Mary's Hospital in London. Besides the appendixes it contains reprints of nine articles on vaccine therapy, on prophylactic inoculation against pneumonia, on tuberculous disease and on immunity published at various times between 1910 and 1942.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

EXPOSURE TO ALUMINUM DUST

To the Editor:—A physician has recently made the statement that an attack of acute bronchitis in an industrial worker was due to exposure to aluminum dust suspended in the atmosphere to which the employee is subjected in the course of his work, citing the presence of aluminum dust particles in the sputum as confirmatory etiologic evidence. Is there any valid evidence that aluminum dust, per se, may act either chemically or mechanically to excite an attack of acute bronchitis or other respiratory infection? I should appreciate a list of references dealing with this subject.

W. N. Dawson, M.D., Maryville, Tenn.

ANSWER.—American medical literature contains no convincing evidence of pulmonary or bronchial injury from exposure to aluminum dust. Occasional roentgenograms showing variable degrees of minor abnormality have been presented as evidence of a specific pneumoconiosis due to aluminum. However, the only report of any group survey in this country is by Crombie, Blaisdell and McPherson (*Canadian M. A. J.* 50:318 [April] 1944). They report no abnormal x-ray observations other than a few cases of healed tuberculosis in 125 men exposed to high concentrations of metallic aluminum powder from six to twenty-three years, with an average of twelve years. Certain German investigators have believed that there is a hazard, although available abstracts of their papers do not contain sufficient information on which to evaluate their conclusions. Goralewski and Kaeger (*Arch. Gewerbepath. u. Gewerbehyg.* 11:102, 1941) state that inhalation of aluminum produces rapidly developing disease that may terminate fatally after eight months of exposure. These authors cite 4 cases presenting x-ray appearances "similar to silicosis" exposed one and a half to sixteen years with dyspnea, in 3 of which spontaneous pneumothorax developed. Koelsch, a competent and experienced industrial hygienist, opposes the view of a specific chemical poisoning. Summarizing his observations on 150 such workmen (*Beitr. z. Klin. d. Tuberk.* 97:688, 1942) he concludes that poor ventilation incident to the blackout and excessive hours of work in young persons is responsible for the abnormal x-ray observations. His opinion of the nature of the condition is not quoted in abstract. Finally Jötten and Eickhoff (*Reichsarbeitsblatt*, part III, No. 32, 1942, *Arbeitsschutz* No. 11) report animal experiments to prove that inhalation over a period of two hundred and thirty-six days results in heavy accumulations of dust in the lungs and associated lymph nodes with "desquamation of alveolar epithelium" and ultimate necrosis of the masses of cells. However, it required superimposed infection with the type I pneumococcus to produce much effect on the pulmonary stroma. Their illustrations strongly suggest the nonspecific reaction that can be produced by excessive concentrations of almost any inert dust. Gardner, Dworski and Delahant (*J. Indust. Hyg. & Toxicol.* 26:211 [Sept.] 1944) did not observe serious effects from prolonged daily inhalations of metallic aluminum or amorphous aluminum hydrate. Injection of excessive quantities of the former into the blood stream blocked the mononuclear phagocytes, so that susceptibility to tuberculosis was increased. Smaller amounts did not have injurious action.

A recent paper by Hunter, Milton, Perry and Thompson (*Brit. J. Indust. Med.* 1:159 [July] 1944) on the effects of aluminum and alumina on the lungs in grinders of duralumin airplane propellers indicates no evidence of pulmonary fibrosis in 92 workers. The films of 7 of the operators revealed certain abnormal shadows in the periphery of the lung fields but these "were not related to symptoms." Their exposure was heavy and 37 of the group had been employed for more than five years. The operation involved grinding and polishing the metallic alloy with aluminum oxide paper. It was the latter which constituted the major portion of the air borne dust; the metallic particles were so large that they settled and few remained suspended in the air.

INSUFFLATION TECHNIC FOR OVIDUCTS

To the Editor:—Would it be safe to use a regular Jarcho Pressometer in the tubal insufflation using atmospheric air after proper sterilization of the apparatus and filtration of the air through sterile cotton placed in the graduated container? I have used this method for pneumothorax therapy but have not heard of the use of a similar technic in tubal insufflation.

A. E. Drexel, M.D., Alexandria, Va.

ANSWER.—Yes, it is absolutely safe.

TOXICITY OF CINCHOPEN

To the Editor:—Please forward information on the toxicity of cinchopen. It has been stated that toxic symptoms develop only several months after taking the drug. Is this possible after taking only one or two doses of 7½ grains each? In other words, can cirrhosis or acute yellow atrophy of the liver develop in two or three months with no intermediate toxic symptoms? Are toxic symptoms infrequent enough to warrant the use of the drug at any time?

Major, M. C., A. U. S.

ANSWER.—A difference of opinion exists concerning the toxicity of cinchopen. Palmer and Woodall (*Cinchopen—Is There a Safe Method of Administration?* *THE JOURNAL*, Sept. 9, 1936, p. 760) in a review of the literature collected 191 cases of jaundice with a mortality of 46.8 per cent following the administration of cinchopen or its derivatives. In some instances small doses caused death; in contrast, large amounts have frequently been given for long periods without ill effects, and some physicians have used cinchopen extensively without having observed any fatalities from its use. The initial symptoms of hepatitis have frequently not appeared for weeks or months after the discontinuance of the drug; in these cases other causes for the hepatitis cannot be entirely excluded. Palmer and Woodall consider that these two factors, the variable relationship between the total dosage and the outcome and the variable length of time between the use of the drug and the appearance of symptoms, account for the varied opinions. Apparently even small doses of the drug given for brief periods may prove fatal, and hence one cannot rely on close observation with withdrawal of the drug on the first appearance of symptoms, for the hepatic injury frequently continues to progress. Palmer and Woodall conclude that there is no safe method for the administration of cinchopen.

BOILS ASSOCIATED WITH MENSTRUAL PERIOD

To the Editor:—A patient has boils within the gluteal folds at each menstrual period. They appear nowhere else on the body and only when the flow is well established. She is 30 years of age and has had the boils for the past twelve years. What is the cause of these boils; are there any references in the literature to the subject?

W. A. Brand, M.D., Redwood Falls, Minn.

ANSWER.—It is difficult to explain the exact relationship between the boils and the menstrual periods; therapy is unsatisfactory in cases like this. Hormone treatment helps a few women but by no means the majority. A simple medication which can be tried is ammonium chloride. Greenhill and Freed have shown how beneficial this substance is in cases of premenstrual tension including localized and generalized edema. The dose is 15 grains (0.97 Gm.) three times a day to be taken after meals for fourteen days before the onset of the next menses. During the time the patient takes the ammonium chloride, she should omit all sodium from her diet; this includes not only table salt but also alkalis, such as sodium bicarbonate.

NUMBER OF CENTENARIANS

To the Editor:—What percentage of people (men and women) in the United States have lived to be one hundred years or more?

J. P. Young, M.D., Chester, S. C.

ANSWER.—According to the returns of the 1940 Census, there were in the United States 3,679 persons 100 years old and over, of whom 1,338 were men and 2,341 women. Of these, 1,411 were white and 2,268 were nonwhite. Although the 1940 figure represents a decrease as compared with the 1930 return of 3,964 centenarians, comprising 1,180 whites and 2,784 nonwhites, the 1940 returns still undoubtedly exaggerate the number. Because persons of advanced age sometimes knowingly report themselves to the enumerator as older than they actually are or, not knowing their true ages, make exaggerated guesses, the reported number of centenarians is no doubt too high, particularly in the nonwhite population.

PARATYPHOID INFECTION

To the Editor:—I have a proved case of paratyphoid B infection with mild complaints. What can be done to cure the patient and protect her family? What can be done to prevent her from being a carrier?

A. L. Henrichsen, M.D., Van Nuys, Calif.

ANSWER.—In this case of paratyphoid B infection the assumption is made that the disease is caused by *Salmonella schottmulleri*. The treatment of this disease is the same as that for typhoid. Triple typhoid-paratyphoid vaccine may be given to contacts in the attempt to increase their resistance to this infection. A course of treatment with sulfadiazine may be instituted in an attempt to clear the carrier state. However, the sulfonamides have not been adequately tested in the treatment of *Salmonella* infections.

TICK BORNE TULAREMIA

REPORT OF FIFTEEN CASES

MAJOR GEORGE V. BYFIELD

CAPTAIN LAWRENCE BRESLOW

CAPTAIN ROLAND R. CROSS JR.

AND

CAPTAIN NOEL J. HERSHEY

MEDICAL CORPS, ARMY OF THE UNITED STATES

Tularemia is an acute infectious disease caused by *Bacterium tularense* (*Pasteurella tularensis*). The disease was discovered in 1910 by Dr. George W. McCoy of the United States Public Health Service. The original investigative work on this "plague-like disease of rodents" was carried out on ground squirrels in Tulare County, Calif—hence the name tularemia. This disease later was found to be present in man and is identical with the "deer fly fever" of man found in Utah.¹ Many cases of human tularemia have been reported. Usually the source of the infection is not difficult to determine.

Tularemia "occurs under natural conditions in over twenty kinds of wild life, especially in wild rabbits and hares. Man becomes infected by contact of his bare hands with the raw flesh and blood of these animals or by bites of blood sucking ticks and flies which have previously fed on animals infected with *Bacterium tularense*."² Experimental transmission of tularemia by mosquitoes has been reported.³

In 1924 Parker⁴ reported that the tick could serve as a carrier of tularemia. Francis cultivated *B. tularense* from guinea pigs which had been injected with ground-up wood ticks (*Dermacentor andersoni*). At that time the data seemed to indicate the possibility of transmission of tularemia from tick to man. Generation to generation transmission of the infection in both *Dermacentor andersoni*⁵ and *Dermacentor variabilis*⁶ has been reported. Interstadial transmission of the infection has been demonstrated in *Amblyomma americanum*.⁷ Since 1924 many cases of tularemia have been reported in which ticks were suspected or proved to have been the transmitting agents.⁸ The ticks more

commonly involved in transmission of human tularemia include *D. andersoni* (the wood tick) and *D. variabilis* (the common dog tick). *A. americanum* (the lone star tick),⁴ *Dermacentor occidentalis*⁷ and *Ixodes ricinus californicus* (Banks)⁸ have been referred to as carriers. The rabbit tick *Hemaphysalis leporis-palustris*¹ is of importance only in transmission of the disease among rabbits.

"Seasonal incidence of cases of tularemia is due to the seasonal variation of three sources of infection—tick bite, fly bite and the dressing of wild rabbits; but, owing to the overlapping of these influences, cases have occurred in the United States in every month of the year."¹ In the Eastern part of the United States the dressing of wild rabbits causes most cases during the months of November and December. Tularemia caused by fly bites occurs principally from June through September. Tularemia caused by tick bites of *D. andersoni* occurs principally from March through August and of *D. variabilis* from January through October.

Of the 600 cases of tularemia reviewed by Foshay⁹ in 1940, 6 were attributed to tick bites. Francis¹⁰ in 1941 reported a total of 53 cases of tularemia in Montana and surrounding states caused by *D. andersoni* and 73 cases principally in the Southern states caused by *D. variabilis*. In addition to these two reports, a review of the literature reveals 20 cases of tick borne tularemia, some of which may have been included by Foshay and Francis.¹¹

All cases herein reported were in soldiers admitted to an evacuation hospital which was receiving patients in a maneuver area in Tennessee. All were admitted between the dates of May 14 and June 12, 1943, a period of thirty days. During operations such as these, soldiers are outdoors almost continuously, sleep on the ground in pup tents and frequently are located in

wooded terrain. All patients had been located in a relatively small area.

Ten patients had definite histories of a tick bite. Most of the patients had a history either of removing ticks which had become attached to their skin, of

remarkable was noted except the general appearance of the skin and the presence of characteristic tularemic lesions. The skin of most patients gave evidence of multiple "insect" bites, attributed to chiggers, mosquitoes, ticks or a combination of these.

The lesions of tularemia, the "punched out" or ragged ulcers and the regional lymphadenopathy varied in location. The earliest tularemic lesions noted were areas of skin 2 to 3 cm. in diameter showing central necrosis and ulceration. The ulcers varied in shape, some having regular edges presenting a punched out effect and others having irregular ragged edges. The early ulcer was usually surrounded by a zone of erythema which was destined to undergo partial necrosis, thereby enlarging the ulcer itself (figs. 1 to 4). Nine patients had typical ulcers. They were located on the leg (6 cases), the arm (1 case) and the chest wall (2 cases).

Thirteen patients had large masses of tender regional lymph nodes, and of these 9 were inguinal or sub-inguinal and 4 were axillary. In cases 14 and 15 small bilateral inguinal lymphadenopathy was noted and these patients had no tularemic ulcers. The enlarged regional lymph nodes were usually 3 to 6 cm. in diameter and protruded 1 to 3 cm. above the surface of the surrounding skin. They were red, moderately

Fig 1 (case 9) —Early tularemic lesion of lower extremity

having found ticks crawling on their bodies or clothing or of having seen or removed ticks from the bodies or clothing of fellow soldiers. This information established firmly the presence of ticks in large numbers and gave some indication of the annoyance they caused.

SYMPTOMS

Histories from the patients indicated an interval varying from one to nine days from the known tick bite until the onset of symptoms. The average interval was five days. However, in view of the probability of multiple exposures, limited reliance must be placed on these figures.

The type of onset was variable. Some patients gave a history of a moderately severe chill followed by a fever as high as 104 F., a severe headache, backache, generalized muscular soreness and "soreness of the bones." Other patients had no chill but complained of general malaise and symptoms similar to those noted during the onset of a mild influenza. They complained usually of pain and tenderness in the area of the regional lymphadenopathy.

PHYSICAL FINDINGS

Examination usually revealed febrile patients with normal sensoriums, the acuteness and severity of the illness varying considerably among them. Some showed a moderate degree of dehydration. Otherwise, nothing

Fig 2 (case 9) —Multiple early tularemic lesions of lower extremity.

firm and, on palpation, varied in their degree of tenderness (fig. 5). Later, in some instances, they became soft and fluctuant as the result of abscess formation.

In case 1 pleural effusion and pneumonia developed. Case 10 showed nuchal rigidity and a positive Kernig's sign. Cerebrospinal fluid was examined and found to be normal. No rashes were noted.

COURSE AND TREATMENT

There were no deaths in our series. The severity of the disease varied widely among the 15 patients. In some instances the disease was a very mild febrile illness; in others it was moderately severe, prolonged

Other than the use of metaphen in 1 case, the surgical drainage of abscesses in 3 cases and the chance use of sulfonamides in 6 cases prior to and 2 cases after admission, no attempt was made to treat the patients other than symptomatically.

COMMENT

The cases we report emphasize the importance of the tick as a cause of human tularemia. The tick, we believe, is too frequently thought of primarily as an intermediate host of Rocky Mountain spotted fever; however, the tick is receiving more recognition in recent literature in connection with Colorado tick fever, American Q fever, tick paralysis and Bullis fever. From a statistical point of view we noted with interest that during the same thirty day period our 15 cases of tularemia were seen only 2 cases of Rocky Mountain spotted fever were admitted to the hospital. Thus tularemia in this particular area was numerically the more prominent of the two tick borne diseases.

In individuals suffering from tularemia due to handling rodents (rabbits principally) the lesions are usually on the upper extremities. In contrast to this, tularemic lesions secondary to the bite of an infected tick are more generalized in distribution, with a predominance of lesions on the lower extremities. In our

Fig 3 (case 6)—Advanced stage of tularemic ulcer of lower extremity.

and debilitating. There was frequently an afebrile period after three or four days followed by a secondary rise in temperature.

In case 1 a pleural effusion and pneumonia developed. Continuous oxygen inhalations were provided and a thoracentesis was performed, 200 cc of dark, straw colored clear fluid being obtained. No other complications occurred.

The leukocyte count varied from normal to a leukocytosis of 16,650 per cubic millimeter. Positive blood agglutinations¹² (complete) ranged from a dilution of 1:320 to 1:1,280, as shown in the table. Diagnostic skin tests were not done. No attempts were made to culture the organism from blood, pleural fluid or pus from incised abscessed glands.

Six patients had received either sulfathiazole or sulfadiazine in varying amounts prior to admission to our hospital. The drug was discontinued on admission. The use of metaphen has been reported by Barthelme.¹³ Ten cc. of a 1:1,000 aqueous solution of metaphen was given intravenously to patient 1 on three consecutive days. We were unable to draw any conclusions as to the beneficial effect of metaphen. Although this type of case usually carries an appreciable mortality, recovery was uneventful in case 1.

In 3 cases abscesses developed in the regional lymph nodes. These became fluctuant and obviously would have drained spontaneously had we not resorted to surgical incision and drainage. This procedure is advisable, we believe, when fluctuation occurs and spontaneous drainage is imminent.

Fig 4 (case 7)—Healing tularemic ulcer of right arm

patients, none of whom had had contact with rodents, the distribution was 9 on the lower extremity and 4 on the upper extremities.

Early in our experience with these cases of tularemia we suspected *D. variabilis* (the dog tick) of being the transmitting agent. Later, however, Dr. Norman H. Topping of the United States Public Health Service

12 Agglutination tests were performed by Dr. W. C. Williams, Commissioner of Public Health, Nashville, Tenn.
13 Barthelme, F. H. "Intravenous Therapy for Tularemia," *J. Chemotherapy*, 1: 317-320 (Oct.) 1937.

carried out a tick survey¹⁴ in an area in which an especially large number of our patients had been bivouacked prior to their illness. He reported that all specimens were *Amblyomma americanum* (the lone star tick).¹⁵ The ticks collected in this survey were tested by Francis¹⁵ and by Parker.¹⁶ Neither was able to demonstrate *P. tularensis* by culture. *D. variabilis* is a proved transmitting agent and is known to be present in the area. It would seem justifiable, irrespective of the results of the survey, to suspect that either or both types of ticks were the transmitting agents among the soldiers involved.

Presumably the infected tick bites its host and feeds for an undetermined period before transmission of the disease occurs. The infectious agent can penetrate the unbroken skin, however, and it is theoretically possible that simple contact of the ticks or the accidental crushing of the tick could cause transmission of the infection. This might explain the method by which the

off and each assist in the thorough inspection of the other's body for the presence of ticks. Ticks should be removed by tweezers or with cotton saturated with iodine. The tick should not be crushed with the bare fingers. The site of the tick bite should be painted with iodine and the hands washed thoroughly after the removal of ticks. One cannot rely on one's sensorium to determine when ticks are attached, as there is frequently an insignificant degree of pain and irritation.

During the forty-five days following the period covered by our report, there occurred 11 additional cases of tularemia.¹⁷ The number of cases may seem relatively small as compared with the number of hospitalizations due to all other causes combined. However, each case of tularemia requires, as a minimum, approximately six to seven weeks of hospitalization and convalescence. The number of days lost due to this disease is obviously great.

CONCLUSION

Fifteen cases of tick borne tularemia in soldiers from an Army maneuver area in Tennessee were seen between the dates of May 14 and June 12, 1943 and presented typical clinical findings of tularemia. The diagnosis was made by clinical picture on admission, a history of exposure to ticks in nearly all instances, a negative history of contact with rodents, a typical clinical course and positive blood agglutinations for *P. tularensis* in 14 of the 15 cases. General supportive treatment was given in all cases, no serologic preparations were used, and all patients recovered. One patient developed a lobar pneumonia and a pleural effusion regarded as specific. Nine cases were of the ulceroglandular type and 6 of the glandular type.

REPORT OF CASES

CASE 1.—A white man aged 23 entered the Evacuation Hospital on May 28, 1943 with a transfer diagnosis of cellulitis of the left scapular area and left axillary lymphadenopathy. He remembered removing a tick from the left shoulder, May 16. A day later he felt ill and had a chill followed by a temperature of 104 F. An ulcer developed on the left shoulder blade followed by tender left axillary lymph nodes. Physical examination revealed an ulcer over the left scapula and very large, tender left axillary lymph nodes. The chest was normal. His fever was septic in type, reaching 103 F. daily for eight days, after which it decreased to 100-101 F. On June 8, following a sudden turn in bed, he became dyspneic and coughed considerably, and his temperature rose to 104 F. Development of a tularemic pneumonia or enlarged hilar lymph nodes causing respiratory embarrassment was suspected. An x-ray of the chest revealed a pneumonia of the right lower lobe. A thoracentesis was performed at which 200 cc. of a dark, straw colored, clear fluid was obtained. A few leukocytes and some cellular debris were noted on microscopic examination. The patient was given continuous inhalation of oxygen. In addition, 10 cc. of a 1:1,000 aqueous solution of metaphen was given intravenously on June 12, 13 and 14. The patient gradually became less dyspneic, improved generally and made a slow but uneventful recovery. The blood agglutination for tularemia was positive in a dilution of 1:640 on June 7. The diagnosis was tularemia, ulceroglandular type, complicated by a lobar pneumonia and pleural effusion, probably specific in type.

CASE 2.—A white man aged 26 entered the Evacuation Hospital on May 14, 1943 with a transfer diagnosis of a severe cellulitis of the left leg, cause undetermined. History revealed that he had become ill about May 4 with influenza-like symptoms. Simultaneously he noted a small "pimple" on his left leg which, instead of "coming to a head," developed into a

Fig. 5 (case 7).—Regional axillary lymphadenopathy in a case of tularemia.

disease was produced in patients not giving a definite history of a tick bite.

The number of civilians exposed to tick bites and the degree of their exposures are usually considerably less than encountered in a military problem such as described in this presentation. Therefore tick borne tularemia is of relatively less importance in the civilian population than in the military service. The problem of prophylaxis against tick borne tularemia is important to the Army particularly and should be approached in a manner similar to that prescribed by the Army for prevention of Rocky Mountain spotted fever. It is suggested that tick infested areas be avoided. Failing this, one should remove ticks from one's clothing and body at least once daily. When soldiers are bivouacked in a tick infested region a thorough inspection of the entire body should be made. Soldiers may be paired

17. Williams, W. C.: Personal communication to the authors.

small ulcer and was accompanied by a painful swelling in the left sublingual region. Fever was noted. Physical examination revealed the presence of enlarged, chronically infected tonsils, an ulcer 1 cm. in diameter on the medial aspect of the lower third of the left leg and an erythematous tender mass just below the left inguinal ligament, approximately 3 cm. in diameter. The temperature was 101 F. Examination was otherwise negative.

The leukocyte count on May 15 was 16,650. He was given 60 grains (4 Gm.) of sulfanilamide daily for four days. Blood agglutination for tularemia was positive in a dilution of 1:1,280 on June 1. His fever of 101-103 F. persisted for five days and dropped by lysis to near normal levels for several weeks. By June 7 the mass in his left groin had become fluctuant, and surgical incision was carried out with the evacuation of much pus. His convalescence was uneventful. The diagnosis was tularemia, ulceroglandular type.

CASE 3.—A white man aged 23 entered the Evacuation Hospital on May 28, 1943 with a transfer diagnosis of an ulcer of the left leg probably due to a tick bite. History revealed that on May 16 he had awakened suffering from severe malaise, fever of 105 F., swollen glands in the left groin and a feeling that "his bones would break." He had removed many ticks from his body during the days preceding admission to the hospital. On May 18 he noted a small ulcer on his left leg, which increased in size until one week prior to admission, when some improvement was noted. Physical examination revealed a temperature of 104 F., a punched out ulcer 1.5 cm. in diameter on the left leg and a large mass of lymph nodes in the left sublingual region measuring 3 by 5 cm. in diameter, firm and indurated but with a fluctuant area in the center. The skin over the mass was red. Blood agglutination for tularemia was positive in a dilution of 1:320 on June 15. Convalescence was uneventful. The diagnosis was tularemia, ulceroglandular type.

CASE 4.—A white man aged 21 entered the Evacuation Hospital on June 7, 1943 with a transfer diagnosis of influenza. History revealed the onset of illness on June 2, when the patient awakened with a high fever and pronounced malaise. He was admitted to a hospital immediately. Two days later he noticed a small furuncle on the medial surface of his right leg and a large tender mass in his right groin. He knew of no tick bite. On admission to our hospital the temperature was 102.5 F. There was a small punched out ulcer 1 cm. in diameter in the midportion of the medial aspect of the right leg. In addition there was a large nonfluctuant mass 3 by 3 cm. in the right sublingual region. Examination was otherwise negative. The leukocyte count was 8,400 and the urinalysis was normal. Blood agglutination for tularemia was positive in a dilution of 1:320 on June 15. Our period of observation of the patient was terminated abruptly after one week, at which time the patient was still febrile. The inguinal lymphadenopathy had increased in degree. A report to us on his progress indicated that the patient made an uneventful recovery. The diagnosis was tularemia, ulceroglandular type.

CASE 5.—A white man aged 22 entered the Evacuation Hospital on June 12, 1943 with a transfer diagnosis of an ulcer of the left flank secondary to a tick bite. History revealed that on June 8 he had found a tick on the lower left chest wall. Two days later he experienced a chill followed by fever, and a tender mass developed in the left axilla. Physical examination on admission was negative except for a punched out ulcer 2 by 3 cm. in diameter on the lower left chest wall and a pronounced left axillary lymphadenopathy, which was tender. He was afebrile during our observation. The blood agglutination was positive in a dilution of 1:1,280 on June 29. Our observation of the case was limited to five days, but subsequent reports indicated that convalescence was satisfactory and uneventful. The diagnosis was tularemia, ulceroglandular type.

CASE 6.—A white man aged 25 entered the Evacuation Hospital on May 28, 1943 with a transfer diagnosis of acute gastroenteritis. The history revealed that he had first reported ill with diarrhea, which started suddenly on May 24 and caused a fever of 106 F. He was treated with sulfaguanidine and bismuth subcarbonate and on May 28 was admitted to our hospital. On admission the chief complaints were fever and

general malaise; the diarrhea had ceased and the stools were formed. The positive physical findings included a small healing superficial abrasion on the left leg as well as one on the right leg. The latter appeared inflamed, was 3 by 5 cm. in diameter and was surrounded by small satellite pustules. There was a very large mass in the right sublingual region interpreted as due to femoral lymphadenopathy. Urinalysis was negative. The leukocyte count was 8,150, with a normal differential. The lesion on the right leg underwent further necrosis, developing into a ragged ulcer. There was a drop in fever from 103 F. to normal followed by a secondary rise maintained for several days. The blood agglutination for tularemia was positive in a dilution of 1:640 on June 7. Recovery was satisfactory when the patient was last seen and it did not appear that the sublingual mass would become fluctuant. The diagnosis was tularemia, ulceroglandular type.

CASE 7.—A white man aged 25 entered the Evacuation Hospital on May 28, 1943 with a transfer diagnosis of a possible tularemia. History revealed that he had had tick bites on his

Laboratory Data

body and right forearm about May 19. Shortly thereafter he had a chill associated with a fever of 104 F., followed by pain under his right arm and a very severe headache. He was hospitalized for ten days at another hospital and released only to suffer a recurrence of his fever. On admission to our hospital the patient was subacutely ill, with a temperature of 101 F. There were two small punched out ulcers on his right forearm and a large tender nodule in the right axilla identified as an enlarged lymph node. Blood agglutination for tularemia was positive in a dilution of 1:320 on June 1. The nodule in the right axilla underwent gradual resolution and an uneventful recovery ensued. The diagnosis was tularemia, ulceroglandular type.

CASE 8.—A white man aged 25 entered the Evacuation Hospital on May 20, 1943 with a transfer diagnosis of an ulcer on the lower third of the right leg, the cause of which was undetermined. History revealed that a nonpainful ulcer had been present for one week, starting as a "rising" and later breaking down and discharging pus. There was no history of tick bites or contact with any rodents. Positive physical findings on admission included a single, painless, discrete, punched out ulcer 1 cm. in diameter on the lateral surface of his right

leg, 8 cm. above the ankle. No varicose veins were noted. The leukocyte count was 8,400 with a normal differential. Urinalysis was negative. On May 25 the patient developed a swelling 6 by 8 cm. in diameter in the right inguinal region, about which there was considerable erythema. Fluctuation, questionable at first, became definite, and since it appeared that the abscess would rupture spontaneously surgical incision and evacuation of a large amount of pus was done on June 7. On June 1 blood agglutination for tularemia was positive in a dilution of 1:1,280. His fever never exceeded 99.6 F., and the patient made an uneventful recovery. The diagnosis was tularemia, ulceroglandular type.

CASE 9.—A white man aged 41 entered the Evacuation Hospital on June 10, 1943 with a transfer diagnosis of tick borne tularemia and an undiagnosed neurologic disturbance. The history of the latter is irrelevant. History revealed that several ticks were removed from his right ankle about May 31 and that on June 5 he suddenly developed a high fever and malaise. Physical findings on admission relative to his tick borne disease included a temperature of 101.4 F., a moderate degree of dehydration, an ulcer over the right patella, two ulcers on the posterior surface of the right leg 3 inches below the popliteal space and a small tender mass in the right inguinal region. The leukocyte count was 12,000 and the urinalysis was negative. During his hospital stay the temperature varied between 99 and 102 F. Blood agglutination was negative for tularemia on June 15. He was transferred to another hospital, where a diagnosis of tularemia was accepted clinically but not proved by repeating the agglutination test at a time when it would have been expected to be positive. Subsequent reports indicate that the patient made an uneventful recovery. The impression was tularemia, ulceroglandular type.

CASE 10.—A white man aged 31 entered the Evacuation Hospital on June 11, 1943 with a transfer diagnosis of possible Rocky Mountain spotted fever. History revealed that his initial complaints included general malaise, headaches, backaches, chills and fever. Later, enlarged painful lymph nodes occurred in the right inguinal region. He had removed many ticks from his body. On admission to the hospital he complained of headache and pain in his abdomen, back and right groin. The patient was febrile, with a temperature of 102.5 F.; he appeared acutely ill and moderately dehydrated. There were many "red areas" on his ankles and feet, indicating recent "insect bites." He had no rash about his forearms, wrists, face, hands or soles. An exquisitely tender mass was present in the right inguinal region. There was pronounced nuchal rigidity and a positive Kernig's sign. The leukocyte count was 8,000 with a normal differential. The spinal fluid examination was normal. A diagnosis was made of tularemia with meningismus. He was given 1,000 cc. of 5 per cent glucose in isotonic solution of sodium chloride intravenously and his fever subsided within four days. Blood agglutination for tularemia was positive in a dilution of 1:1,280 on June 28. Subsequent reports from another hospital indicated an uneventful recovery. The diagnosis was tularemia, glandular type.

CASE 11.—A white man aged 32 entered the Evacuation Hospital on June 4, 1943 with a transfer diagnosis of a left axillary lymphadenitis probably secondary to a tick bite. History revealed that he had found and partially removed a tick from his left axilla on May 15. The head apparently remained buried despite attempts made at the aid station to remove it. Ten days later he developed a mass in the left axilla 2 by 5 cm. in diameter and projecting 2 cm. above the surface. On admission the patient was ambulatory and afebrile and did not appear acutely ill. There was no ulcer nor evidence of a recently healed ulcer. The leukocyte count and urinalysis were normal. By June 7 the mass in the left axilla had become fluctuant and was incised. Blood agglutination for tularemia was positive in a dilution of 1:320 on June 7. No fever exceeding 99.6 F. was recorded and the patient made an uneventful recovery. The diagnosis was tularemia, glandular type.

CASE 12.—A white man aged 25 entered the Evacuation Hospital on May 29, 1943 with a transfer diagnosis of tick bites on both lower extremities and the lower trunk. History

revealed that the patient had noticed a tick in his left groin on May 8. He removed the tick, but the head remained buried in the skin and subsequent infection about it necessitated surgical incision on May 14. At this time several small "kernels" were noticed in his left groin, which gradually increased in size. On May 26 the patient had a chill followed by a temperature of 103 F. He was admitted to a hospital, given sulfadiazine for two days and then transferred to our hospital. Examination on admission revealed a temperature of 100.4 F., and several tick bites on the extremities and abdomen, one on the left flank being infected. The inguinal glands, particularly on the left, were enlarged and tender. The leukocyte count was 12,300. The patient received sulfadiazine for four days without apparent improvement. His fever subsided gradually to near normal levels after eight days and then rose to 101 F. for several days before subsiding. The blood agglutination for tularemia was positive in a dilution of 1:1,280 on June 15. Convalescence was uneventful. The diagnosis was tularemia, glandular type.

CASE 13.—A white man aged 28 entered the Evacuation Hospital on May 28, 1943 with a transfer diagnosis of nasopharyngitis and acute lymphadenitis of the left inguinal region, the cause of which was undetermined. History revealed that about May 14 the patient had removed several ticks from his legs. On May 23 he was admitted to a hospital because of a sudden onset of pronounced malaise, chills and fever. Several days later he noticed a painful swelling in his right groin, for which he was transferred to our hospital. Physical examination revealed a temperature of 102.6 F., scattered musical rales in his chest, a tender swollen mass in his right inguinal region and two circumscribed indurated areas about 1 cm. in diameter on his left thigh. No ulcer was present. The leukocyte count was 11,000. His temperature decreased from 102.6 F. to normal in four days, remained normal for three days and rose again to remain moderately elevated for the next two weeks. Blood agglutination was positive for tularemia in a dilution of 1:640 on June 7. The patient made an uneventful convalescence. The diagnosis was tularemia, glandular type.

CASE 14.—A white man aged 27 entered the Evacuation Hospital on June 11, 1943 with a transfer diagnosis of fever of undetermined origin. His complaints included fever, headache, pain and swelling in both groins and some diarrhea. The history revealed that these complaints had been present for two days and that he had removed several ticks from his body during the past month, the most recent one being removed two days prior to admission. Positive physical findings included a temperature of 100.6 F., insect bites on his chest, abdomen and legs, and an indurated area in the right groin attributed to a tick bite. There was no ulcer, but the lymph nodes in both groins were enlarged, discrete and tender. On June 26 the blood agglutination for tularemia was positive in a dilution of 1:640. The patient's temperature remained elevated during the period of our observation, but subsequent reports indicated that he made an uneventful recovery. The diagnosis was tularemia, glandular type.

CASE 15.—A white man aged 28 entered the Evacuation Hospital on May 28, 1943 with a transfer diagnosis of nasopharyngitis. History revealed that the patient had been in a region heavily infested with ticks and had removed several from his lower abdomen and thighs. On May 26 he became ill with malaise, chilly sensations and slight pain in the right inguinal region. Physical examination on admission revealed that the patient was febrile and appeared moderately ill. The inguinal nodes were bilaterally enlarged, discrete and slightly tender. On the left side of the abdomen and on the anterior aspect of the upper third of the thigh were found small crusted lesions attributed to tick bites. The leukocyte count was 7,100. The patient's temperature became normal on the third hospital day and remained so until the eleventh hospital day, when the temperature rose to 100.6 F. The temperature remained elevated for two days, after which it again returned to normal and remained normal until discharge from the hospital. No ulcer was seen at any time. Blood agglutination for tularemia was positive in a dilution of 1:1,280 on June 15. The patient made an uneventful recovery. The diagnosis was tularemia, glandular type.

NONMAGNETIC INTRAOCULAR
FOREIGN BODIESHARVEY E. THORPE, M.D.
PITTSBURGH

The greatly increased number of intraocular foreign body cases resulting from the accelerated industrial war effort and the nature of ocular combat injuries makes this subject of special interest to the ophthalmologist today.

With the acceleration of industry has come the employment of huge numbers of unskilled, inexperienced personnel and a relative laxness in protective and preventive measures (goggles, shields, and so on).

There has also been an increase of such cases in civilian life with wider use and misuse of poor quality tools, especially hammers, chisels, hatchets and improvised hand tools. We have seen this in patients coming from the farm and home.

Moreover, the number of nonmagnetic foreign body cases has increased both in industry and in combat. Industry is now making greater use of various nonferrous metals and nonmagnetic alloys. The recognition by German and Italian forces in the early days of the North African desert campaigns that steel land mines and booby traps were readily discovered with magnetic locators resulted in the substitution of copper, other nonferrous metals and even bakelite in their construction, according to Stallard.¹ The resulting explosions of these mines and of other bombs in combat and aerial warfare have caused many new problems for the ophthalmic surgeon.

Whereas the magnet was the miracle tool for the magnetic intraocular foreign body, it was worthless for high manganese steel alloys, for copper, brass, lead, aluminum, wood and other substances. (Frequently the ophthalmologist threw his hands up at seeing a case with nonmagnetic intraocular foreign body. However, with improved x-ray localization and improved surgical technics a number of such eyes can be saved from blindness.)

A number of problems face the ophthalmologist in every case of ocular injury by solid bodies:

1. What should lead one to suspect an intraocular foreign body?
2. What are the external clinical evidences of such?
3. Should x-ray photographs be taken?
4. What is a rapid and simple method of x-ray localization?
5. Are there methods aside from the history to tell one whether one is dealing with a magnetic or a nonmagnetic particle?
6. Should the magnet be used for diagnosis?
7. How should one proceed with nonmagnetic foreign bodies in an attempt to save the globe?
8. What foreign bodies may remain undisturbed?
9. What are useful measures for prevention of infection?
10. What are essential safety measures during operation?
11. What steps can one take to prevent retinal detachment incident to transscleral surgery?
12. What about sympathetic ophthalmia?

I shall attempt to answer some of the foregoing and other related questions that deal with nonmagnetic intraocular foreign bodies. It does not necessarily follow that an eye containing a piece of copper or brass is doomed and should be treated by enucleation. Measures and technics are available which will save many of these cases, and every resource must be used, especially when both eyes harbor foreign bodies or when only one seeing globe remains.

It is also my purpose in this paper to review the various procedures that I have found useful in removing over seventy nonmagnetic foreign bodies from the cornea, anterior chamber, iris, lens, ciliary body, sclera and vitreous.

HISTORY

To begin with, a detailed history of injury is extremely important. Any eye that was injured while the patient was hammering, drilling or working with moving machinery or was exposed to flying particles from another workman's tools, to an explosion or to the shattering of any solid (glass, wood or metal or the like) should be considered as possibly harboring an intraocular foreign body. A careful description and examination (where possible) of the tools and objects that were employed at the time of injury helps in differentiating magnetic from nonmagnetic fragments. Stallard,¹ writing about the North African desert campaign, found that the analysis of exploded bomb fragments lodged in the face gives a clue as to the nature of the possible intraocular foreign body. We may thus often have a clue as to whether a foreign body is magnetic or nonmagnetic or whether it is glass or some other substance. At times it is possible to discover in questioning the patient the approximate size of the offending particle and the course it took toward the eye, coming from below or above or from the right or left.

The removal of foreign material from the conjunctival sac or corneal surface should by no means lull our senses into dismissing such a case without further careful investigation. Too often does one see instances in which a so-called corneal foreign body was removed or nothing was found and the patient dismissed, only to turn up later with siderosis, cataract or blindness.

The Clinical Examination.—The visual acuity of both eyes should be recorded when possible. A careful examination of the entire anterior segment for evidence of perforation is paramount. This must be done with both loupe and slit lamp microscope. (A drop of pontocaine facilitates this.) A perforation of Bowman's and especially Descemet's membrane leaves permanent tell-tale evidence. A small bloody blotch on the sclera shortly after injury may be the only evidence of perforation. A further careful search with the ophthalmoscope gives valuable information about the iris, lens, vitreous and retina. With the instruments mentioned one can often follow the trajectory and course of the flying particle in the eye and thus help to localize it. One should remember, however, that occasionally flying particles may recoil from the sclera into an unsuspected part of the vitreous chamber.

The examinations also reveal degenerative and chemical pigmentation changes such as siderosis or chalkosis.

A knowledge of the tension in early injuries gives information about the presence of a leaking wound. It is of course easier to recognize and diagnose cases shortly after injury. This is particularly true in small

Read before the Section on Ophthalmology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

scleral perforations, which may heal within a few days and defy recognition.

The transilluminator is valuable in discovering iris holes and even holes in the ciliary body and choroid.

Both eyes must be carefully examined. It has happened thrice in my experience that a patient coming in with an injury of one eye harbored a foreign body in the other. All methods of examination should be employed.

X-RAY LOCALIZATION

In any case in which there is the possibility of an intraocular foreign body being harbored x-ray examination should be made first for diagnosis and then for localization. And every case in which there is a history of hammering, shattering or explosion should be so suspected, even when clinical examination is negative. When the diagnostic x-ray is negative when taken posteriorly to anteriorly in the chin-nose position it should be repeated with several different exposures so as to give films of different densities and angles. Small foreign bodies sometimes show up in this manner. Of course only x-ray opaque substances, such as metals, show up. Glass, wood and plastics do not show up in x-ray films of the eye. An extremely valuable procedure for foreign bodies in the anterior segment is Vogt's² "skeleton free or bone free" method for soft tissue technic. A dental film or a small special shaped film is held along the side of the nose and pressed into the inner canthus. The lids are drawn apart and a profile x-ray film of the exposed globe is taken from the temporal side. The film can also be pressed into the lower fornix and the eye rayed from above. This method shows up minute foreign bodies in the anterior chamber angle or anywhere in the anterior segment. It will even show glass if taken with soft rays. More of the anterior half of the eyeball can be exposed by producing artificial proptosis with 2 to 4 cc. of procaine hydrochloride or isotonic solution of sodium chloride injected retrobulbar. Comberg's³ contact lens method of x-ray localization has deservedly gained in popularity in recent years. It is simple and accurate if performed with reasonable care. Its chief proponent in this country has been Pfeiffer.⁴ A drop of tetracaine hydrochloride 0.5 per cent is instilled in the conjunctival sac. The contact lens bearing four lead markers is inserted between the lids and two exposures are taken, viz. a lateral exposure with the involved eye nearest the film and a posteroanterior exposure with the head in the chin-nose position. For the posteroanterior view the patient looks into a small pocket mirror on the x-ray table at the reflection of either his injured or his healthy eye. If the eyes are not parallel or only one eye is present, a cover glass on a black cardboard triangle wedge base serves as an angle mirror in which can be seen an adjustable reflected light source, such as a pocket flashlight. The purpose, of course, is to have the visual axis perpendicular to the film and the central x-ray passing through the visual axis. The chief objection to the Comberg lens is that it does not always lie coaxially with the cornea; another is its fragility when dropped. In the past three years I have frequently used a plastic⁵ localizing shell, similar to the Comberg

lens. To obviate displacement of the lens on the globe, I recently modified the Comberg lens by having suture holes drilled near the lens edge, so that it may be anchored with episcleral sutures. A vent hole was also placed in the corneal portion near the limbus to help break suction adherence, which occasionally impedes removal of the contact lens. The plastic lens is useful if one is interested in localization only. The glass lens, however, has certain advantages for visualization of the globe. It outlines the anterior portion of the globe and when studied in stereoscopic⁶ lateral and posteroanterior views gives one an excellent idea as to the topographic location of the ocular foreign body. It has given me a better tridimensional concept. On reading a draft of Spaeth's⁶ paper before this section two years ago, I was impressed with the value of stereoscopic x-ray pictures of the eye when air had been injected into Tenon's space according to the method of Gasteiger and Grauer abroad and Spackman⁷ of Philadelphia. This air injection method we combined with the Comberg glass lens.⁸ The entire globe was thus outlined when viewed stereoscopically, and borderline cases of double perforation became more readily diagnosed.

X-ray localization must be extremely accurate, for it controls the method of approach and the site of the globe incision in these cases. The Comberg and Vogt methods are simple, rapid and accurate. They can be performed with a minimum of apparatus. Brigadier Graham's x-ray localization method⁸ with a 12 mm. diameter silver wire ring sutured to the limbus has proved valuable in the handling of eye injuries in the African desert campaign. Spaeth⁶ uses silver rings of several diameters sutured to the globe for x-ray localization. Sweet's localizer is an accurate method requiring special apparatus.

An eye may harbor two or more foreign bodies. This happens occasionally in civilian life and more frequently in combat injuries, and sometimes this complicates localization. Stokes mentions that in 300 cases of intraocular foreign bodies the x-ray examination was negative in 2.5 per cent of cases. It is possible that Vogt's method or variation of exposure technic might show up some of these negative cases (which evidently harbored minute or flat foreign bodies lying parallel with the horizontal plane of the eye). The methods used formerly for differentiating nonmagnetic from magnetic foreign bodies aside from the history and examination of tools and analysis of fragments taken from the face¹ or other parts of the body in explosion injuries consisted of the magnet test. This is a dangerous method because the magnet during the test may pull the foreign body into the ciliary or lens or may wedge it deeper. The magnet should never be used as a test except when the x-ray localization is completed and the method of approach is decided on, and then only in the operating room when one is ready to proceed with surgery.

THE BERMAN LOCATOR

We have in the past six months used a Berman locator.⁹ This is an extremely valuable instrument, first, for determining whether an intraocular foreign

body is magnetic and, second, for localizing the magnetic foreign body. It was used originally at Pearl Harbor by Moorhead¹⁰ in December 1941. Minsky¹¹ recently described its application for the transscleral approach. I have found it valuable for localization in 4 magnetic cases and found its usefulness in differentiating a non-magnetic vitreous foreign body. It has not proved useful in localizing small nonmagnetic foreign bodies. My interest was attracted to it by having seen it used at the New York Eye and Ear Infirmary in the fall of 1943.

Glass and other chemically inert foreign bodies, such as aluminum and stainless steel alloys, apparently do not irritate the eye. And when they are in relatively inaccessible positions or when they do not produce mechanical irritation or pressure they are best left alone.

Copper and its alloys and most iron particles are extremely dangerous to the eye. It is well to follow the generally accepted dictum ably expressed by Snell¹² to employ every reasonable attempt to remove a non-magnetic foreign body, if the surgery does not cause excessive mutilation of the eye. It is well to see these cases early, to do all necessary examinations immediately and then to decide whether surgery or expectant conservative treatment had best be followed for the time being. Where an attempt at removal of multiple intra-ocular foreign bodies would mutilate the globe, discretion would prove the better part of valor.

PREPARATION OF PATIENT FOR SURGERY

A barbituric sedative, such as 1½ grains (0.1 Gm.) of pentobarbital, is given one hour before operation, if it is to be done under local anesthesia. The skin is cleansed in the usual manner.

The local anesthesia and akinesia is performed as follows:

1. Topical instillation of 3 drops of 0.5 per cent tetracaine, or pontocaine, hydrochloride at intervals of one minute.
2. Subconjunctival injection of 2 per cent procaine hydrochloride containing 1/30,000 epinephrine. It is often valuable to inject the superior rectus.
3. Retrobulbar injection of 1 cc. of 2 per cent procaine with 1/30,000 epinephrine between the lateral and the inferior recti.
4. Akinesia by (a) O'Brien's method: injection 10 mm. in front of the ear notch (incisura intertragica), 3 to 4 cc. of 2 per cent procaine with 1/75,000 epinephrine (1 minim of 1/1,000 epinephrine in 5 cc. of procaine); (b) VanLint's method; injection of aforementioned procaine and epinephrine mixture at the lateral border of the orbit.
5. Lateral canthus injection of 0.25 cc. of procaine-epinephrine mixture to facilitate canthotomy if necessary.

For general anesthesia, sodium pentothal intravenously or solution of tribromoethanol with ether proves adequate.

Retrobulbar injection and akinesia may be omitted when the globe is not to be opened.

CORNEA

The method of removal of foreign bodies from the cornea depends on their depth, which is determined with the narrow beam of the slit lamp. An angled spud working at the edge of the embedded corneal foreign body so as to pry it out is a relatively simple procedure. Where there are multiple foreign bodies the 1 millimeter curet is extremely useful in their removal.

When a sliver of brass or wood lies between the corneal lamellas it can be extracted with a splinter forceps having special teeth. I have found this useful in the past ten years (fig. 2). Sometimes it becomes necessary to cut down through the overlying lamellas and to pry the splinter loose. It is very important to remove wood splinters or thorns thoroughly, as they cause prolonged irritation. Multiple small fragments of coal or glass completely enclosed in corneal stroma are well tolerated and may remain undisturbed.

Fragments in the pupil zone of the cornea that have penetrated partly into the anterior chamber are best handled by following Kuhnt's suggestion. The pupil is contracted with physostigmine. A narrow keratome such as Agnew's or Castroviejo's is inserted into the anterior chamber across the pupil zone and anchored in the opposite side to prevent injuring the lens capsule. One then cuts down with a knife needle until the foreign body is reached (fig. 3). It is then removed with the aforementioned corneal splinter forceps. Penetrating fragments outside the pupillary zone are reached by performing a corneal section with a Graefe knife or keratome and scissors. The corneal flap is turned inside out and the projecting splinter is removed with the aforementioned forceps (fig. 4). The corneal incision is closed with previously inserted corneoscleral sutures. A conjunctival flap may be prepared previous to performing the corneal section.

ANTERIOR CHAMBER

Nonmagnetic foreign bodies lying loose in the anterior chamber can be removed through a keratome incision in the particular quadrant where the foreign body lies. The anterior chamber should always be restored with the chamber irrigator (isotonic solution of sodium chloride). If the corneal incision is near the limbus, a corneoscleral suture should be used to prevent iris prolapse. The Mendoza type of suture or a mattress suture may be employed. The Burch corneal pic and the Hoffman pic are useful in suturing corneal lacerations. Atraumatic needles are very helpful.

CHAMBER ANGLE

Most foreign bodies in the anterior chamber lodge in the lower angle, and sometimes they are wedged there and covered by exudate. They can be seen with the diagnostic chamber angle contact lens if they lie behind the scleral ledge. To remove them, keratotomy is made to the side and the foreign body is pried loose with a blunt Tyrell iris hook (fig. 5a). After which it is removed with the serrated nontoothed iris or clot forceps. Lancaster has suggested making a corneal section forward with a narrow Graefe knife and then reaching into the angle with the clot forceps (fig. 5b). Meller suggested the application of a corneoscleral trephine over the foreign body and hinging the button (fig. 5c). After the foreign body is removed with forceps, the corneoscleral button can be replaced with a suture.

IRIS

Nonmagnetic foreign bodies embedded in iris tissue should be disentangled with forceps through a keratome incision. If this is impossible, or when the iris is traumatized excessively, the portion of iris containing the foreign body should be excised.

LENS

Foreign bodies in the lens cause traumatic cataract. Sometimes this is slow in developing. However, because of the low metabolic lens activity, lenticular foreign

bodies are well tolerated. To remove such fragments one might employ Donovan's¹³ method, described before this section in 1925. A gage 19 hypodermic needle is inserted into the lens through a small keratome incision up to the foreign body, and suction made with the attached syringe plunger. On the other hand, the usual practice is to wait until the lens becomes opaque and deliver it in capsule. Older patients may have the

the upper equatorial portion of the lens with counter pressure below according to the method of Pagenstecher (fig. 6). A small amount of vitreous loss may take place at times. But this is guarded against by previously inserted corneoscleral sutures.

If the foreign body lies near the anterior capsule and one is timid about the intracapsular extraction, it is good practice to grasp the nonmagnetic particle and its overlying capsule with the toothed capsule forceps. If the foreign body is lost in the depths of the lens, it may be located with the transilluminator applied to the sclera. (The pupil should be maximally dilated.)

FOREIGN BODY IN POSTERIOR AQUEOUS CHAMBER

Accurate localization is essential. A Gayet incision is made with Lundsgaard's knife. This can be done externally or subconjunctivally with a previously dissected flap. The McLean corneoscleral suture is inserted. Iridodialysis at the root is performed with pointed scissors and the iris is pulled out of the way with the blunt Tyrell hook. The corneal flap is lifted up. The foreign body is grasped with the serrated blades of the clot forceps. It is sometimes seen enveloped in exudate.

NONMAGNETIC PARTICLE IN CILIARY BODY

Here again accurate x-ray localization is paramount. A conjunctival flap including Tenon's capsule is dissected from 10 mm. behind the limbus forward. The sclera is exposed and the exact spot for incision marked with gentian violet. A meridional incision with a number 15 Bard Parker blade is made in the sclera overlying the foreign body. This is facilitated by inserting a Mendoza suture after the first few strokes and having the assistant pull up on both sides of the loop. This helps to pull the sclera away from the ciliary body. Burch's method for making a scleral incision may be used by having parallel episcleral sutures, one on each side of the incision and drawing up on them. The incision is made carefully and deliberately. It is made 4 to 5 mm. long and may be enlarged with Stevens scissors. If one now pulls up on the scleral sutures so as to open the incision, the foreign body may appear in the wound (fig. 7). For hemostasis it is now useful to place a drop of thromboplastin and a drop of 1:100 solution of epinephrine between the lips of the incision. One waits a few moments for the foreign body to appear. If the foreign body lies deeper in the ciliary body, that can now be incised radially. If the particle is seen it can be seized with serrated dressing forceps. Aid may be had from the Lancaster or Lange

transilluminator applied to the opposite side of the globe. If the ciliary body prolapses, it is abscised. The incision is closed with the aforementioned Mendoza suture. The conjunctiva is replaced and closed with running silk sutures. I have employed both methods

successfully on several occasions. In passing, one should mention the pars plana approach according to Verhoeff's¹⁴ and Fralick's¹⁵ methods for magnetic particles.

FOREIGN BODY IN VITREOUS

An eye with a piece of copper or brass in the vitreous was formerly given up as lost. Today instruments and methods are available for salvaging many such eyes. Several methods are applicable, depending on the location of the foreign body and on its visibility with the ophthalmoscope. The prognosis is affected materially by its location. Foreign bodies close to the optic nerve offer a poorer prognosis.

VITREOUS: FIRST METHOD

When the lens is clear and the foreign body is visible with the ophthalmoscope without excessive rotation of the globe it can be approached through a meridional transscleral incision and grasped with the author's¹⁶ self-closing vitreous forceps (figs. 8 and 9). This forceps is constructed so that it has no moving blades in the incision and thus does a minimum of trauma to the neighboring retina and choroid.

The conjunctiva and Tenon's capsule are dissected from the globe after the quadrant of location of the foreign body is selected. The point of election for scleral incision is marked with gentian violet. A rectangular area 8 by 4 mm. is now outlined, with scleral surface coagulations (fig. 10) to prevent retinal detachment. An I or T shaped incision is made with the long axis meridionally in the sclera by gradual dissection with a number 15 Bard Parker blade. An episcleral suture on each side of the incision pulls the sides of the incision up. The choroid and retina are opened with the diathermy knife. The incision can, however, be made with a shallow thrust of the Graefe knife. The length of the incision need not be more than 4 to 6 mm., depending on the size of the foreign body. Sometimes it appears in the wound as glistening metal or covered by exudate. In such a case it is grasped with small

moscope and grasps it with the author's self-closing vitreous chamber forceps introduced through the incision. The foreign body is removed and the incision closed as described. The wound may be touched with trichloroacetic acid or 95 per cent phenol¹⁷ (or with the fused potassium hydroxide pencil and neutralized with 3 per cent acetic acid). The conjunctiva is closed with a running suture.

Fig. 12.—Ophthalmic endoscope: self-luminous instrument for removal of nonmagnetic intravitreal foreign bodies.

VITREOUS: SECOND METHOD WITH OPHTHALMIC ENDOSCOPE¹⁸

I devised this instrument in 1934, first in the non-luminous form, and presented it before this section¹⁹ in the same year. Shortly thereafter I designed a self-luminous endoscope for removal of intravitreal nonmagnetic foreign bodies. This later model was demonstrated at the October 1934 meeting of the American Academy of Ophthalmology and Oto-Laryngology. I have used it successfully in 4 cases. It has also been used with success clinically by Spaeth⁶ and others.

The ophthalmic endoscope consists of (1) a light carrier with a very small miniature lamp, (2) a special inverted Galilean telescope 2.5 mm. in diameter and (3) a small tubular forceps held together in a straight line by a metal sheath. In cross section the working end of the instrument measures 2.5 by 6.5 mm. The telescope affords a field of view 60 degrees in diameter, so that at 15 mm. distance the field is 15 mm. in diameter, at 20 mm. distance the field is 20 mm. in diameter, and so on. Thus, two thirds of the interior of the eye can readily be covered by moderate tilting of the instrument. Objects at a distance of 15 mm. from the telescope objective lens are magnified 2 diameters. The magnification increases with proximity to the telescope. The lens system is so constructed that objects in the field of view are in focus at all distances from 1 to 25 mm. Thus all instrumentation can be observed directly.

Various forceps are supplied with the instrument. Some have serrated jaws with smooth edges for grasping irregular shaped splinters, others have small cup shaped jaws or ring shaped jaws for lead BB shot. The adjustable sheath may be preset for the desired depth of forceps penetration into the globe.

Fig. 11.—Method of holding ophthalmic endoscope during operation: F, forceps blades; H, forceps operating hand; T, telescope; L, miniature lamp; S, adjustable sheath; E, eyepiece; C, electric connection to battery rheostat.

forceps and the scleral incision immediately closed with the aforementioned sutures. If it does not appear in the wound, one visualizes the particle with the ophthal-

19. Thorpe, H. E.: Ocular Endoscope, *Tr. Sect. Ophth., A. M. A., 1934*, p. 290.

PRELIMINARY PRACTICE WITH THE ENDOSCOPE

The most important factor in the application of the endoscope is to become thoroughly familiar with its use by working inside a small light proof pill box 1 inch in diameter, approximate in size to the eye. Since the instrument is monocular, that is a handicap one learns to overcome during practice. Then one should practice with pig's eyes into which a foreign body such as a lead shot has been inserted through a scleral incision. The same incision may be used for the endoscope. The lamp is connected by a cord to a preset battery or rheostat. The ophthalmic endoscope is cleansed with green soap and water. It is rinsed in distilled water and sterilized by immersing the instrument and the connecting cord in 1:1,000 mercuric oxycyanide or 1:3,500 mercuric phenyl nitrate for twenty minutes. After rinsing in distilled water and wiping dry, it is ready for use. Heat sterilization, alcohol and other sterilizing chemicals (except the ones advised) will damage the lens cement and the electrical insulation and thus ruin the instrument.

When used in the operating room, the instrument is applicable to most cases in which the vitreous is not too bloody or muddy with exudate. X-ray localization by either Sweet's or Comberg's method is performed first. The sclera is exposed in the quadrant of localization preferably between two muscles or beneath the inferior or superior rectus (never beneath the lateral or medial recti because of the long ciliary arteries). A rectangular area 4 by 8 mm. with its long axis meridional is plotted on the surface of the sclera in the quadrant of attack. The sides of this rectangle are now outlined with scleral surface coagulations 2 mm. apart. These are made either with the 1 mm. diameter flat surface electrode or with the short Kronfeld diathermy needle electrode. A meridional I shaped scleral incision 2 by 7 mm. is now prepared with a number 15 Bard Parker scalpel, cutting down just to the choroid. Two Mendoza sutures are placed in the lips of the scleral incision. With these sutures the assistant can either pull the flaps of the incision open or he can shut them. Epinephrine 1:100 and thromboplastin are now dropped onto the choroid to produce a bloodless field. After a few moments the field is sponged dry. The choroid and retina are now incised the full length and shape of the scleral opening with the cutting current or with a small Graefe knife, using a shallow thrust. One now waits a few moments for the foreign body to appear in the wound. (It sometimes does, while the lips of the wound are held up with the aforementioned silk sutures.) The endoscope held in the left hand, with lamp lit, forceps controlled with right thumb and index finger, is now guided to the wound. The surgeon puts his eye to the eyepiece just as he places the working end of the instrument within the lips of the incision. He must be just within the retina or he cannot see the interior. The forceps must be kept closed and pulled up within 2 to 3 mm. of the telescope. The assistant prevents any deeper thrust of the body of the instrument while the surgeon inspects the interior of the globe in his search for the foreign body. As he is searching, he has the forceps blades turned slightly to one side. Once the foreign body is found, the surgeon gradually pushes the grasping forceps toward it, opens the forceps blades and allows the forceps to close slowly onto the foreign body. The forceps, with the foreign body retained by its self-closing spring action, is pulled up to the telescope under direct vision and the whole instrument

is now removed from between the lips of the wound. Little or no vitreous is lost if the telescope is not pushed into the vitreous body. During the entire procedure one assistant also keeps the scleral lips closed against the endoscope with the aid of the sutures mentioned. As soon as the foreign body is removed, the sutures are tied, closing the scleral incision. If necessary, additional sutures may now be inserted with the aid of the Burch pic or bident. The conjunctiva is closed by a running suture. The fundus may be inspected if the lens is clear to note the position and status of the retina. The postoperative treatment that I follow is the same as the one generally used for retinal detachment. After three to four weeks the patient is given Lindner Stenopaic spectacles. Of 4 patients operated on by this method, 1 has 20/30 vision, another has 20/100 vision, a third with originally bloody vitreous and a large ciliary wound has in the past five months come up to counting fingers and the fourth has a soft eye with no light perception.

Considerable interest has recently been shown in this method by military and naval medical officers as well as by ophthalmologists in civilian practice.²⁰

VITREOUS: THIRD METHOD

Scleral Incision and Transillumination.—This method was suggested in the presentation of the first (non-luminous) model of the ophthalmic endoscope in 1934.¹⁹

A scleral incision is prepared as is usual for the transscleral approach with addition of surface diathermy for prevention of retinal detachment, as described in the second method. One or two transilluminators are placed on the opposite walls of the globe, and as one inspects the open incision one may see the foreign body shadow. It is grasped with small dressing forceps. The sclera is closed with previously inserted sutures. This method has proved useful to me in 2 instances. Schutz²¹ has recently applied this method. Lindner²² recommended this approach.

In commenting in general on surgery of the vitreous, it is paramount not to grope in the vitreous blindly. It is highly important not to fish around in and generally lacerate the vitreous. The forceps should be small and simple acting and should approach the foreign body directly by the shortest and most feasible route. One must guard against damaging the retina and other vital structures. One must have a definite plan of approach and modus operandi, worked out on the basis of accurate localization. This is best done in form of a sketch or diagram.

VITREOUS: FOURTH METHOD

Biplane Fluoroscope and Cross²³ Forceps for Removal of Lead Shot.—I have had no personal experience with this method because of the lack of a biplane fluoroscope. In the hands of Cross, with the aid of his fluoroscopist, the method has proved successful in several cases.

SCLERAL FOREIGN BODIES

Generally if they do not penetrate into the globe, scleral foreign bodies may be allowed to remain undisturbed. However, should removal be necessary, an accurate localization with careful plotting comes first,

20. The manufacturer of the instrument is American Cystoscope Makers, Inc., 1241 Lafayette Avenue, Bronx, New York.

21. Schutz, J. A.: Removal of a Nonmagnetic Foreign Body from the Vitreous, *Am. J. Ophth.* 25: 70 (Jan.) 1942.

22. Lindner, Karl: Personal communication to the author, 1935.

23. Cross, G. H.: Removal of a No. 6 Lead Shot from Within the Eyeball by Specially Devised Forceps with the Aid of the Double Plane Fluoroscope, *Tr. Am. Ophth. Soc.* 25: 80, 1927.

followed by gradual cutting down on the indicated point in the sclera. If the foreign body is not visible on the surface, it is well to palpate the site of the projected incision with the end of a muscle hook to note the presence of a hard foreign body.

Orbital foreign bodies do not come within the scope of this paper. Most of them can remain undisturbed, unless large or making pressure on vital structures or causing pain.

The postoperative treatment is as follows:

1. *Foreign Protein Therapy.*—(a) In fresh injuries, on admission to the hospital 10 cc. of boiled milk is injected intraglutely for men, 8 cc. for women and appropriate lesser doses for children. Twenty million of typhoid antigen A intravenously may be substituted for the 10 cc. of milk dose and correspondingly for lesser doses. This may be repeated every third or fourth day for four to six doses. The typhoid antigen dosage is increased 20 to 40 to 60 million, and so on as required. (b) Older injuries receive the foreign protein therapy within six hours after intraocular surgery.

2. *Sulfonamides.*—Sulfadiazine is employed. In fresh injuries an initial dose of 2 Gm. is followed by 1 Gm. every four hours for twenty-four to forty-eight hours. Thereafter 1 Gm. is administered every six hours for two to three days. The dosage is figured 0.1 Gm. per kilogram of body weight. The blood cell count (red and white) and the urinalysis are performed every forty-eight hours during sulfonamide medication. The sulfadiazine blood level is also watched.

3. *Position in Bed.*—The patient is usually kept flat in bed for forty-eight hours for all wounds of the cornea. Scleral wounds or incisions require absolute rest for six to seven days. Incisions or wounds in the lower part of the globe require three to four days longer rest in the supine position.

4. Atropine is used (after checking tension) in all cases except foreign bodies in the anterior chamber or those projecting from the cornea into the anterior chamber. However, it is used routinely in all postoperative foreign body cases except when an existent primary glaucoma contraindicates its use.

5. Dressings every other day are routine except in traumatic cataract (or traumatic iritis), when they are done daily for mydriatic instillation.

6. *Stenopaic Lindner spectacles* are used for eight to sixteen weeks in all transscleral wounds posterior to the ora serrata.

SYMPATHETIC OPHTHALMIA

Every penetrating ocular injury should be watched for a year or longer for early evidences of sympathetic ophthalmia. This means careful slit lamp and ophthalmoscopic examination of both eyes at frequent and regular intervals. The use of foreign proteins, asepsis, the sulfonamide drugs and careful excision of prolapsed uveal tissue have caused a definite reduction in the occurrence of this dread disease. One must constantly be on the lookout for all the clinical evidences of this disease. Enucleation should not be delayed in the hope of saving a severely mutilated or hopelessly damaged globe when sympathetic ophthalmia is a likely probability. One should remember that the slit lamp gives reasonably early warning of developing sympathetic disease.

CONCLUSIONS

Chemically inert intraocular foreign bodies need not be disturbed unless they produce mechanical irritation. They sometimes cause glaucoma.

Differentiation of magnetic from nonmagnetic foreign bodies can be aided by the history of the injury, examination of the tools employed and use of the Berman locator as well as by examination of fragments from the face or other exposed parts of the body in explosion cases. The use of the magnet for diagnosis is bad practice and should be deprecated.

A simple x-ray technic is afforded by the Vogt and Comberg methods. A modified Comberg lens as described gives more certain localization and avoids pitfalls.

Stereoscopic x-ray films with localizing shell give a tridimensional concept of the foreign body position. When combined with air injection in Tenon's space, they help in diagnosing double perforations.

Multiple intraocular foreign bodies suggest conservative therapy for the time being when they exceed three in number.

One must avoid mutilating a globe simply for the sake of removing a foreign body that may be inert.

Retinal detachment must be properly and promptly treated.

Prompt removal of intraocular foreign bodies is important.

In using the ophthalmic endoscope, one must practice on numerous animal eyes to master the technic. Properly used, the endoscope is a valuable aid to our armamentarium for saving a potentially lost eye from a retained nonmagnetic foreign body.

One should never grope in the vitreous with any instrument.

Infections must be prevented and treated by asepsis, assurance of patency of the lacrimal passages, foreign proteins and sulfonamide drugs.

Foci of infection should not be overlooked in causing delayed healing and complications, such as uveitis.

The topical use of 1:100 epinephrine and thromboplastin helps to check oozing hemorrhage.

Removal of an injured eye is indicated only when it is collapsed or extensive loss of vitreous has taken place and light perception is gone.

Corneal and scleral lacerations heal earlier and better when sutured. The wound may also be covered by a conjunctival flap in addition to suturing.

One should remember to examine carefully the fellow eye at the first and subsequent visits: It may harbor a foreign body from the same or a previous accident. Both eyes should be watched routinely with slit lamp and ophthalmoscope.

Sympathetic ophthalmia should be kept in mind in every perforating case.

500 Penn Avenue.

ABSTRACT OF DISCUSSION

DR. E. B. SPAETH, Philadelphia: The accurate x-ray localization of a magnetic foreign body is relatively unimportant as long as we know (1) the size and the shape of the foreign body, (2) whether the foreign body is intraocular or extraocular and (3) perhaps whether it is anterior or posterior to the iris-ciliary body-lens diaphragm. A careful history of the situation and circumstances present at the time of the accident plus the x-ray intensity or density of the foreign body will probably clear up the question of whether or not the foreign body is a magnetic one. Conversely, the most accurate x-ray localization possible should be obtained for nonmagnetic foreign bodies. Even if one foreign body is fully visible with the ophthalmoscope, with the slit lamp or with oblique illumination one still does not know whether or not others, not visible, may be present. The fact to be emphasized is this: the use of any and all means available for localization, radiopaque markers, scleral rings, contact glasses, iodized oil and air injections, molded films and filtered x-rays, are all necessary though perhaps not in any 1 individual case. An eye which is hopelessly destroyed, sightless and collapsed should be removed as soon as possible. It shortens the period of hospitalization and permits an earlier return of the patient to social and economic activities. Sympathetic ophthalmia does not develop ordinarily

surgical or medical care because of persisting difficulties. All of the cases have been carefully followed for a period of two to fourteen years, and the present status of each one is well known by us.

The inclusion of a fairly large series of patients operated on elsewhere who later developed difficulties in our own personally supervised group of patients depresses the over-all picture. These cases are unsatisfactory not necessarily because of originally poor sur-

gical judgment or operative procedures but because of the difficulties inherent in the surgical management of ileitis and the tendency of the disease to recur post-operatively in new segments of small bowel or often in the colon. The inclusion of cases of high ileitis or of localized jejunitis, as well as cases of combined ileitis and colitis, still further complicates the statistical review of a large group of patients and dampens the enthusiasm which the simpler and more direct treatment of the original terminal forms of ileitis seemed to inspire. However, after an experience with 164 cases covering a period of fourteen years, we felt that it was important to review again our material as thoroughly as possible in order to appraise the late results of the surgical treatment of this disease.

the primary operation and the severe recurrence. A late recurrence has already been noted by Bockus¹ in a similar type of case in which nine years intervened before the lighting up of the original disease in a new segment of the small intestine. In this group the primary operative mortality rate is appreciable (16.3 per cent) but late follow-up studies show a distressingly high rate of recurrence.

Ileocolostomy Group.—An ileotransverse colostomy or ileosigmoidostomy with transection of the ileum was carried out in 65 cases with no operative death. Nine recurrences of the disease must be recognized, a recurrence rate of 13.8 per cent. Here the mortality rate of the operation is nil, but again a fairly high recurrence rate is evident although the figure is considerably less (13.8 per cent) than that following primary resection (19.5 per cent). A short-circuiting procedure without transection of the ileum was not performed in this series because it was recognized early that transection of the ileum well above the lesion is essential to a satisfactory result.

Two Stage Ileocolic Resection.—This graded type of operation consists of a primary short-circuiting ileocolostomy above the lesion with transection of the ileum followed after a period of time by resection of the original area of disease in the terminal ileum and cecum and ascending colon. There were 25 patients

gical judgment or operative procedures but because of the difficulties inherent in the surgical management of ileitis and the tendency of the disease to recur post-operatively in new segments of small bowel or often in the colon. The inclusion of cases of high ileitis or of localized jejunitis, as well as cases of combined ileitis and colitis, still further complicates the statistical review of a large group of patients and dampens the enthusiasm which the simpler and more direct treatment of the original terminal forms of ileitis seemed to inspire. However, after an experience with 164 cases covering a period of fourteen years, we felt that it was important to review again our material as thoroughly as possible in order to appraise the late results of the surgical treatment of this disease.

ANALYSIS OF RESULTS

Primary Resection.—A primary resection of the disease process, usually of the pathologic terminal ileum and the adjacent normal ileum and ascending colon, was performed in 55 cases. Nine patients died post-operatively. Of the remaining 46, 9 developed recurrences in the ileum above the point of anastomosis (ileotransverse colostomy or ileosigmoidostomy), a recurrence rate of 19.5 per cent. Some of these recurrences have not been severe, and except for diarrhea and some loss of weight the patients have been treated

medically in a fairly satisfactory manner. The fact that we have encountered no late mortality in this group indicates that, once the risk of immediate operation has been overcome, life itself is assured, although physiologic intestinal function and general weight, strength and efficiency may be impaired.

The larger incidence of recurrence not hitherto recognized is due in large part to the longer period of follow-up. In this group we note a case of recurrence eight years after the original observation and another instance of recurrence twelve years after the first surgical procedure. In both instances, eight and twelve years of perfect health and function intervened between

in this group, with 3 postoperative deaths, a mortality of 12 per cent. We note 8 instances of recurrent disease in the surviving 22 patients, a rate of 36.3 per cent. The second of these two stage procedures was often necessitated by the lack of success of the first or short-circuiting operation. The operative risk was therefore greater and the likelihood of recurrence similarly enhanced in spite of the second more radical procedure. In the combined cases of ileocolitis in which the ileum and some segment of the colon, usually ileum and cecum or ileum and ascending and transverse colon, are involved the magnitude of the surgical procedure or procedures is greater, the risk is increased and the results are more dubious. Nineteen cases of combined ileocolitis are included in this group. There were 2 operative deaths and 3 instances of recurrence of the disease. Finally we include in this series 2 cases of multiple resections of the ileum for concomitant disease in two widely isolated segments of the small bowel. One patient is well and 1 developed a recurrence.

If we analyze separately the cases treated at Mount Sinai Hospital and those at other institutions, a disparity of figures becomes evident. This may be explained in part by the larger number of cases in 1 instance as compared with the other. Thus, in the Mount Sinai Hospital series there were 45 cases of ileocolic resection with 6 deaths, or 13.3 per cent, and 6 recurrences, 15.4 per cent. There were 57 patients in the ileocolostomy group with no operative mortality and

1. Bockus, H. L.: Gastro-Enterology, Philadelphia, W. B. Saunders Company, 1944, vol. 2, p. 192.

6 recurrences, a rate of 10.5 per cent. In the two stage resection group there were 16 cases with 2 deaths, a mortality of 12.5 per cent, and 4 recurrences, or 28.6 per cent. In the group of combined ileocolitis there were 19 patients with 2 deaths, a mortality of 10.5 per cent, and 3 recurrences, or 17.6 per cent. In the group treated at other hospitals 10 resection cases were followed by 3 deaths, a mortality of 30 per cent, and 3 recurrences, or 43 per cent. There were no deaths in the group of 8 ileocolostomy cases, but 3 recurrences, 47 per cent. In a group of 9 two stage resections there was 1 death, or 11 per cent, and 4 recurrences, or 50 per cent.

GENERAL OBSERVATIONS

Operative Mortality.—In the entire group of 164 cases, regardless of the complexity of the procedures involved, there were 14 deaths, an operative mortality of 8.5 per cent. The low operative risk for intra-abdominal procedures of such magnitude bespeaks the successful advances in surgical judgment, technic, anesthesia and preoperative and postoperative care.

The Choice of Operation.—We have collected enough material to permit an evaluation of the relative merits of primary resection as compared with short-circuiting procedures. We note 55 primary resections with 9 operative deaths and a recurrence rate of 19.5 per cent. In comparison, we have 65 short-circuiting procedures with no operative death and a recurrence rate of 13.8 per cent. The greater safety of the less radical procedure and its smaller rate of recurrence would weigh the balance strongly in favor of the more conservative operation.

Is it correct to term an ileotransverse colostomy or an ileosigmoidostomy with transection of the ileum a "palliative procedure"? "Palliative" would indicate an incomplete or a temporary measure, short of permanent cure. Such a term as applied to a short-circuiting procedure for the relief of regional ileitis is a misnomer, for in the course of the 25 instances in which a two stage resection was undertaken the specimen, when finally removed after a variable interval, showed in almost every case complete healing. In the interval between the two operations, abdominal inflammatory masses rapidly dissolve, abdominal wall fistulas heal and enterovesical communications close spontaneously. The resected specimens show advanced healing, scar replacement, a shrinkage of the lumen of the intestine and cessation of evidences of inflammation.

Why, then, was the second stage or resection undertaken? Either because the two stage procedure had been planned and adopted as the operation of choice and was carried through as per schedule because, in the judgment of the surgeon, conditions warranted the completion of the assignment, or persistent diarrhea or some localized discomfort or pain or delay in the restoration of full weight and strength seemed to indicate the removal of an area which might be a residual focus of disease. Also, because of the not infrequent recurrence above the anastomosis, it was originally thought that the secondary removal of the original source of infection would reduce the incidence of recurrences.

The two stage operation has been generally discarded for three reasons: (1) because in most instances the resected area of ileitis was found inactive and healed and fistulas spontaneously closed, (2) because in spite of the second stage resection the percentage of recurrence remained as high as if not higher than following

the simple short-circuiting procedure and (3) because in the group of the 25 cases of two stage resections we noted 3 deaths, an appreciable mortality.

In the earlier years of the surgery of ileitis, resection was preferred because, without the pathologic examination of the resected specimen, the actual diagnosis of the lesion could not be established beyond a reasonable doubt. The suspicion of intestinal tuberculosis was always suggested, and only the histologic and bacteriologic confirmation or denial would suffice to establish the nonspecificity of the lesion. With growing experience and confidence, the surgeon was able to identify and recognize ileitis as such and could with confidence short-circuit the lesion and return the diseased bowel to the abdomen without invoking criticism and without entailing the additional risk of a more radical procedure.

The Question of Recurrence.—It is difficult to explain satisfactorily the relatively high rate of recurrence proximal to the new anastomosis. Two possibilities immediately suggest themselves: Either the surgeon is unable to recognize the most proximal of the skip lesions before transecting the ileum or the recurrent focus starts from a nidus of infection outside the intestinal wall proper. With increasing experience the surgeon should be able to demonstrate all skip areas, knowing that these are characteristic features of the disease. This demands, in every case, a careful examination at the operating table of the entire small intestine. It is possible, however, that some skip areas may be so small as to escape the attention of the most experienced and alert technician. If this is the explanation, then a much wider area of small intestine must be excluded in order to circumvent any inclusion of disease above the anastomosis, a decision which might invite serious diarrhea and nutritional disturbances because of too much exclusion of mucosal absorbing surface. It has been suggested that the recurrences are due to residual infection outside the intestinal wall, the main suspicion being directed to the mesenteric lymph nodes. The fact that the recurrence rate is just as high, if not higher, after radical resection with excision of the mesenteric lymph nodes would seem to imply that these lymph nodes are not responsible for the recurrences. Furthermore, if the lymph nodes in the mesentery were the source of recurrent areas it would be necessary to hypothecate spread against the lymphatic flow, a most unusual event in the pathologic sequence of inflammation in man. It must be emphasized further that secondary operation, on many occasions, has disclosed complete recession of previously enlarged nodes after a simple ileocolostomy.

The Clinical Significance of Recurrences.—The diagnosis of recurrence is suggested by the presence of diarrhea, fever and loss of weight and is confirmed by radiographic demonstration of irregularity in the segment of ileum proximal to the new anastomosis. This is best demonstrated by the barium enema. In many of these so-called recurrences the basis for such a diagnosis is the roentgenographic demonstration of a distorted mucosal pattern or irregularity of outline of the "new" terminal segment of ileum. In many of these fever is absent, diarrhea is moderate, weight is maintained and the hemoglobin content of the blood is unaffected and the patient functions as an efficient member of society. Many of these so-called recurrences are "radiographic" recurrences only and the diarrhea is not more excessive than is consistent with the increased number of movements that characterize any shortened intestinal tract. These patients do well with general

supportive measures, such as diet, rest, liver extract and vitamin B injections, and they often improve with succinylsulfathiazole or sulfathaladine as chemotherapeutic agents. A large number of patients suffering with mild recurrences of the radiographic type have been under observation for some years and remain comparatively well. One wonders whether, in the absence of active symptoms, the x-ray is the final criterion for making a diagnosis of recurrence. However, in appraising the cases reported in this paper we have classed every one presenting x-ray evidences of ileal distortion characteristic of the disease as a recurrence. Cures by surgery in ileitis are often so complete that we have records of 3 patients who have been admitted to the armed forces of the country and are serving in perfect health.

No satisfactory medical treatment of ileitis exists. Chemotherapy has not been proved to be generally satisfactory in this disease; penicillin has not been released in sufficient quantity for a fair trial, although there is little scientific reason to believe that penicillin will be curative.

Until the cause of the disease is discovered, the treatment of ileitis remains surgical. The future improvement in the results of the operative treatment of ileitis will rest on earlier diagnosis and more prompt operative intervention. With earlier diagnosis on the part of the physician and with greater experience on the part of the surgeon, especially as regards the choice of operative procedure, the future should hold promise of far better results.

50 East Seventy-Seventh Street—1075 Park Avenue.

ABSTRACT OF DISCUSSION

DR. HENRY W. CAVE, New York: Of the primary resections in 55 cases there were nine deaths. Of the 46 that did survive 9 developed recurrences, a recurrence rate of 19.5 per cent. Although these recurrences have taken place, some were not too severe and were treated by medical management. This is a high rate of recurrence following primary resection. As always, the longer the period of follow-up, the larger number of recurrences are discovered. There were 2 late recurrences, 1 eight years, the other twelve; both of these patients maintained perfect health and function between the time of primary operation and the time of recurrence. In the ileocolostomy group (which they now advocate) they had 65 patients. In this group of 65 patients there was no mortality, a commendable surgical achievement. They report a smaller group of 25 cases in which a two stage ileocolic resection was done. In the 22 that survived there was a surprisingly high recurrence rate of 36.3 per cent. The second stage procedure was performed frequently for the reason that the short circuiting maneuver previously had failed to cure the patient. Nineteen patients in this group were suffering from a combined lesion, "ileocolitis"; in other words, the ileum and the ascending or transverse colon were diseased. Considering the severity of this particular lesion, they were fortunate in having only two operative deaths. For the entire group of 164 patients there were fourteen deaths, an admirably low operative mortality of 8.5 per cent. They attribute this low mortality rate to advances in surgical judgment, anesthesia and preoperative and postoperative care. I think it was due to their wide experience with this disease and their own sound judgment in handling each difficulty. They admittedly cannot explain the high recurrence rate proximal to the anastomosis. They suggest that it is due to the fact that the surgeon does not discover involved areas higher up before transecting the ileum or perhaps that the point of recurrence is outside the intestinal tract and is not demonstrable. From the impressive number of cases and the figures shown of low mortality and low rate of recurrence, one would agree that in their hands, at least, the operation of choice is ileocolostomy with exclusion.

DR. CLAUDE F. DIXON, Rochester, Minn.: I agree that the results in some cases of nonspecific enteritis in which there is recurrence are discouraging. Recurrence is not invariably due to a diseased segment of bowel being overlooked at the time of resection but to the fact that often the disease develops in a heretofore normal segment of bowel. I believe that infection is not primarily the cause. Over a two years period my colleagues and I attempted to isolate a causative organism but to no avail. The same holds true with regard to a virus as a possible factor. In attempting to find a substance to which patients suffering from nonspecific enteritis are sensitive or allergic I have observed that many of them are sensitive to whole milk. Could this be the cause? Resection of the diseased segment of bowel is the procedure of choice. The exclusion type of ileocolostomy in my experience has not brought about complete recovery. It does in some instances produce an apparent abatement of the disease in the short circuited segment of intestine followed by general improvement of the patient's condition, but, on the other hand, I have had some patients who returned with an extension of the disease. When a fistula occurs, for example between the diseased segment of intestine and the urinary bladder, ileocolostomy in many of my cases has not brought about spontaneous closure of the communication between the bladder and the intestine. I have had the same experience with several cases in which an enteroabdominal fistula was present; therefore I still perform resection. In 3 of my cases there were so-called recurrences four to eight years after resection. Nonspecific enteritis usually occurs among high strung, nervous persons not unlike that group of patients among whom duodenal ulcer frequently develops. During the past six years my colleagues and I have performed resection (most often a one stage procedure) in 108 cases of nonspecific enteritis with only two deaths.

DR. BURRILL B. CROHN, New York: Most of the mortality in resection was the result of poor judgment. Resection in the presence of multiple fistulas and localized peritonitis, resection performed in the presence of well defined abscesses are likely to head one for disaster. In the course of time short circuiting surgery was introduced. At first I was disappointed with the fact that short circuiting was performed and the disease process was allowed to remain. In those earlier years I advocated and urged secondary resection. Now, with the review of this series of cases, I am convinced that the less surgery the better, the safer for the patient. Short circuiting alone, leaving aside the original disease, is probably the best procedure. I should like to go on record against the pessimistic figures in the literature. These data are published by men who accumulate hundreds of figures by reading various articles, lumping them all together and attempting to draw conclusions. The follow-up is here entirely insufficient and the statistics are therefore not likely to be reliable. We lack experience with penicillin; we think well of the sulfonamide drugs; I am still an enthusiastic supporter of the surgical approach to the disease. The future carries a greater promise of more satisfactory results because most of the cases of ileitis, as we see them today, have had courses ranging from two to ten or even twenty years before surgery was approached. If, in the future, the diagnosis can be made without the lapse of such an interminable time, and if the surgical approach is direct and takes place soon enough in the life history of the disease, I think the end results of surgery will be gratifying.

First Cesarean Section.—The first cesarean section on record was performed by an Italian physician, Christopher Bain, in 1540. Jeremias Trautmann of Wittenberg, Germany, first described the technic of the operation in detail. His patient died three weeks after the operation. James Gullencan (1550-1609) performed the operation in the presence of Ambroise Paré (1510-1590) in the year 1590 (?). His patient died during the operation. The famous surgeon Paré advised against the operation. Strange as it may seem, the first successful operation for cesarean section was performed in 1500 by Jacob Nuffer, a layman, on his own wife.—Gordon, Benjamin Lee: *The Romance of Medicine*, Philadelphia, F. A. Davis Company, 1944.

ARMY CONTRIBUTIONS TO POSTWAR VENEREAL DISEASE CONTROL PLANNING

LIEUTENANT COLONEL THOMAS H. STERNBERG
AND

CAPTAIN GRANVILLE W. LARIMORE
MEDICAL CORPS, ARMY OF THE UNITED STATES

It is even now apparent that the approaching demobilization period will be accompanied by many serious problems in the control of the venereal diseases. During and following previous wars the incidence of venereal disease always reached epidemic proportions. While the maintenance of low military rates during the first three years of the current conflict justifies a feeling of achievement by all concerned, it is noteworthy that since the 1st of January 1944 the Army venereal disease rate for the continental United States has risen steadily to a present level of 36 per thousand men annually as compared to the 1943 rate of 26.3. Furthermore, it is our belief, based on the following considerations, that the Army rate in the continental United States will continue to rise for some time and may even reach World War I levels:

1. It is increasingly evident that a general letdown in the overall venereal disease control program, both military and civilian, is in progress.

2. The outstanding advances in therapeutic methods climaxed by the introduction of penicillin have resulted in (a) better reporting of venereal disease with a decrease in the amount of concealed gonorrhea, (b) a definite but as yet unmeasured effect on the will of the soldier to avoid venereal disease and (c) a reduction in the man days lost per thousand men annually from 1,280 in 1940 to a current record low of less than 300, giving rise to a further loss of interest in prevention.

3. As the result of overseas assignment, the group of young trained venereal disease control officers initially stationed in this country has been depleted almost to the vanishing point. While this has lowered the intensity of our venereal disease program at home, it is with a great deal of satisfaction that the downward trend of the venereal disease rates in all theaters of operation is recorded. The combined overseas rate for all American soldiers is now lower than for those stationed in the United States.

4. Troops returning from overseas areas have had an abnormally high venereal disease rate of infection, acquired after arrival in this country. This is an increasingly serious problem. It can be explained in part by the effects of long overseas duty and by the belief of these men that the girls in this country are free of infection.

It is obvious that these problems affect the civilian and military alike and present a rather gloomy picture for the immediate future. Despite this, it is our opinion that in the postwar period there will exist an unprecedented opportunity to reduce the incidence of the venereal diseases to a manageable minimum. This opportunity, to be fully exploited, will require a critical evaluation of our current control measures with a view toward their strengthening and expansion and a recognition of the changing aspects of venereal disease control brought about by more effective therapeutic weapons and by the

mass wartime experience with educational and case finding procedures.

It is believed that in the planning for postwar venereal disease control the Army has much to offer in the way of material assets and experiences. It is our intention in this paper to discuss specifically these contributions not only with respect to actual demobilization procedures but also in relation to the strictly civilian activities of venereal disease education, case finding and community action.

DEMobilization PLANS

During the past six months the Army, in collaboration with the U. S. Public Health Service, has developed demobilization plans in respect to venereal disease which may be outlined as follows:

1. A physical examination for venereal disease and a routine serologic test for syphilis will be performed on all soldiers within the forty-eight hours prior to their discharge from the Army.

2. All soldiers with gonorrhea and chancroid, and those with evidence of active syphilis, either early or late, will be held and treated. They will be treated until cured or, in the case of syphilis, they will receive a course of penicillin which is believed to be curative but which in any event will render the patient noninfectious.

3. Referral will be made to appropriate state health departments through the U. S. Public Health Service of (a) the name and civilian address of previously untreated soldiers found at the time of separation to have latent syphilis as evidenced by a positive serologic test and (b) all pertinent information on soldiers under treatment or previously treated by the Army, provided further medical attention is considered necessary.

The application of this plan to over seven million soldiers will be of considerable value to the overall civilian program in that it represents (1) a mass case finding procedure, (2) a uniform method of transition of partially treated or incompletely observed cases from the Army to the civilian, (3) a mechanism for detecting the previously unidentified failures to the prescribed course of treatment and (4) a method of obtaining a final evaluation of Army treatment schedules, both mapharsen-bismuth and penicillin.

In such a mass procedure some errors are bound to occur. Some of the positive tests will on investigation prove to be technical or biologic false positives, and it is important that these individuals shall not be considered syphilitic until proved so by subsequent examination. Further, it is inevitable that an occasional case of infectious syphilis or gonorrhea will escape identification during the final physical examination or will be in the incubation period at that time.

MEASUREMENT OF TRENDS

Unfortunately, our present methods of measuring incidence of infectious venereal disease in civilian populations, based on reported cases, are subject to so many errors that they are difficult to evaluate. On the other hand, the incidence rates for venereal disease in the Army reflect to a considerable degree the incidence of infectious venereal disease in the civilian community and may therefore be used in determining trends in the civilian population.

While the total Army venereal disease rate in the continental United States has risen sharply since the 1st of January, 1944, a breakdown by disease reveals the increase to be entirely due to gonorrhea. The epidemiologic picture in this disease is far from encouraging. The recent 40 per cent increase in the Army gonorrhea rate must reflect, at least partially, an increase in the

Read before the National Postwar Venereal Disease Control Conference, St. Louis, Nov. 9, 1944.

From the Venereal Disease Control Division, Preventive Medicine Service, Office of the Surgeon General, U. S. Army.

incidence of civilian gonorrhea. Since military data invariably show a ratio of 6 to 7 cases of gonorrhea to 1 of syphilis, it may be assumed that a similar ratio prevails in the civilian population. If this assumption is true, it suggests that an enormous amount of unrecorded and presumably untreated gonorrhea exists in the civilian population and indicates the relative inadequacy of our present gonorrhea control program.

However, during the past year the Army syphilis rate has declined 20 per cent. It is hoped and believed that this decline is due to a lowering of the civilian reservoir of infectious syphilis brought about through the admittedly better case finding technics in this disease, plus the effect of the rapid treatment programs.

POSTWAR PERSONNEL RESOURCES

These figures on the disproportionate decline in syphilis and increase in gonorrhea present encouraging evidence of success in the syphilis control program which should serve as a stimulation to even greater efforts toward the elimination of this disease. They also, of course, indicate the great need for the development of an effective gonorrhea control program. The accomplishment of these objectives will to a large extent depend on the availability and proper utilization of trained or experienced personnel, and the Army will contribute greatly to this task.

Availability of Experienced Physicians During Demobilization.—During the war several thousand medical officers have received formal training or experience in the control of venereal disease and in general public health procedures. The majority of these officers were general practitioners in civilian life and will return to their offices when released. They should be encouraged to continue their interest in and support of venereal disease control as an aspect of preventive medicine. The role of the private practitioner in the control of the venereal diseases has been underemphasized. It is vital to the success of the overall program that a better relationship between the health officer and the physician be established to the end that every physician is either his own adequate epidemiologist or permits access to his patients of an accredited health department representative.

Utilization of Army Lay Venereal Disease Control Officers.—A second contribution the Army will make to civilian postwar personnel resources will be several thousand enlisted men who have had extensive training and experience in the nontechnical aspects of venereal disease control procedures. Many of these have devoted most of their Army service to taking contact histories and have become very proficient in this task; others, both white and colored, have acted as noncommissioned venereal disease control officers with considerable distinction; more than a thousand are graduates of formal courses in venereal disease control for noncommissioned officers, given at several Army posts during the past three years. The value of male nonmedical contact follow-up personnel has been demonstrated in several state health departments as well as in the Army, and it is believed that health departments and clinics should consider the employment of these individuals as they are demobilized.

INFLUENCE OF TREATMENT ON CASE FINDING

An important factor that has had a definite influence on case finding in the Army has been the introduction of penicillin in the treatment of gonorrhea. When

penicillin was first made available to the Army for the treatment of this disease, many soldiers with successfully concealed infections voluntarily reported at sick call and asked for penicillin treatment. This experience would seem to have considerable significance to civilian case finding programs, indicating that at the proper time widespread publicity in respect to the availability of penicillin and its nontoxicity and effectiveness will result in many hidden sources of infection voluntarily seeking treatment.

POSTWAR COMMUNITY ACTION

During the past few years community organization and action toward the control of the venereal diseases, stimulated and assisted by the military, federal and voluntary agencies, has reached a peak of popular support and interest which will be difficult to maintain. As the end of the war approaches it is becoming increasingly evident that the danger of a serious letdown in these activities is imminent. Since in the postwar period Army support of community action will no longer have either the influence or authority as during the wartime period, it is believed urgent that all agencies and local groups concerned immediately direct their planning toward peacetime activities, justified on the basis of a permanent community need, rather than as a temporary aid to the Army in time of war.

Influence of Army Personnel in Postwar Community Programs.—In the Army, commanding officers of all grades are charged with the responsibility of maintaining health in their organizations, and by regulation they are, with the advice and assistance of the surgeon, specifically delegated the task of development and maintenance of venereal disease and preventive medicine control programs. The so-called command aspect of public health practice carries down through the noncommissioned officer to the enlisted man, and the subject is included in all training courses. Thus demobilization will return to the communities hundreds of thousands of officers and millions of enlisted men who have had first hand knowledge of the principles of preventive medicine. Many of these men are the civic leaders of tomorrow, and every effort should be exerted to assure their active participation and support in all phases of community action directed toward the control of venereal disease.

VENEREAL DISEASE EDUCATION

During the past few years the Army has enjoyed a unique experience in being able to apply, on a compulsory basis, intensive venereal disease educational procedures to large masses of men. This program, beginning at the time of the soldier's induction and carrying through to his discharge, is carried out by commanding officers, medical officers and chaplains, utilizing every accepted method of approach.

It is significant in terms of the overall civilian educational program that the Army alone will have returned to civilian communities by the end of demobilization over 9,000,000 men who have been subjected to this instruction, a circumstance which will, we hope, raise the general venereal disease educational level of the nation to a new high. With these men as a nucleus, an opportunity exists to remove forever the venereal diseases from the realm of the unmentionable.

Because of current publicity and conflicts over education as a venereal disease preventive measure it seems desirable that the Army mass experience in this phase of venereal disease control be made available. The

amount and variety of venereal disease education to which the average soldier is exposed is certainly larger and more concentrated in point of time than is currently applied to the civilian population. Further, it has been possible through observations of individual organizations to formulate opinions as to the value of various educational materials and methods of presentation. Some of these are here offered as being of possible significance in the planning of future civilian venereal disease educational programs.

First, it must be recognized that there are two distinct and separate phases of venereal disease education, (1) the imparting to the individual of adequate technical knowledge of the venereal diseases and their prevention and (2) the motivation of the individual with the will to avoid either illicit sexual intercourse or unprotected sexual exposure. Much of the confusion as to the actual role of education, and no small part of the criticism that has been leveled against it as a venereal disease preventive measure, arises from a failure to consider these two aspects as separate entities.

It must be admitted that an individual cannot intelligently protect himself against venereal disease if he does not know what the diseases are, how they are spread and the correct methods of prevention, including continence. Yet it must also be accepted that the possession of merely technical knowledge is no assurance that it will be used when needed. We have seen not one but literally thousands of examples demonstrating that possession of mere technical knowledge of the venereal diseases is of limited value as a preventive measure and that, to be effective, venereal disease educational procedures must also impart a motivation for the avoidance of venereal disease. This motivation involves complex and in many instances intangible factors, which in the Army are related to such diverse conditions as the religious and educational background of the soldier, the influence of the home and the community, the attitude of his commanding officer, the *esprit de corps* of his unit, fear of the diseases or their treatment, fear of shame or ridicule and many others, over most of which the Army has little direct control.

The Army, through the Corps of Chaplains and through venereal disease educational material, has continuously stressed continence as the most desirable and satisfactory method of avoiding venereal disease. Yet the strictly moral approach has been of limited value. This is attributed, at least in part, to the fact that molding of character and establishment of standards of personal conduct should and must be accomplished by the home, the church and the community at an earlier age. Because venereal disease is a biologic accident of the sex act an effective moral program will prevent infection, but the imparting of proper standards of personal conduct to the individual is not venereal disease education in the sense in which we are using the term and should not be so considered. Therefore the role of the physician and health officer in venereal disease control programs is necessarily limited. He can assume responsibility for the dissemination of scientifically accurate information and for the provision of adequate treatment, prophylactic and epidemiologic facilities. He can and should support and assist those educational programs designed to influence sex behavior; but he cannot be expected to assume primary responsibility for the development of moral integrity.

PROPHYLAXIS

In the Army there seems strong reason to believe that the condom has been the most valuable single venereal disease preventive measure, as evidenced by the extent of its utilization.

Chemical prophylaxis administered at a fixed station, on which great reliance has been placed in theory and in past practice, has been difficult to popularize in this emergency because of the frequent inaccessibility of stations, the time consumed in administering treatment, the messiness, occasional discomfort and lack of privacy. Early in 1943, in an effort to improve individual chemical prophylaxis, the Army in collaboration with the Subcommittee on Venereal Diseases of the National Research Council set about to develop a single tube chemical prophylactic, effective against syphilis, gonorrhea and chancroid. After considerable experimentation an ointment containing 15 per cent sulfathiazole, 30 per cent calomel, 40 per cent petrolatum, 14 per cent light mineral oil and 1 per cent cetyl alcohol was subjected to field trials at six army posts in lieu of the regular station prophylaxis. The instructions were simple and the entire procedure required only several minutes, was acceptable cosmetically, was unaccompanied by discomfort and was easily self administered. At all six of the trial stations the prophylactic rate doubled or tripled merely through the spread by word of mouth that the Army had a new and improved prophylactic. This material has now become a standard Army prophylactic item distributed under the name of Pro-Kit.

It would appear from this experience that one important reason for the failure of individual chemical prophylaxis to take in civilian life has been the unsatisfactory products available and that postwar venereal disease control planning will be incomplete without provisions to make this item freely available at a price commensurate with its cost of production.

VENEREAL DISEASE CONTROL IN NEGROES

The Negro venereal disease rate in the Army has consistently been higher than the white rate. Negro troops have received the basic venereal disease control program given to white troops, and additional specific measures have been directed from a national level. These have been ineffective in lowering the overall Negro rate. However, successful Negro venereal disease control programs are possible on a local level, as demonstrated by the consistently low rates maintained at Tuskegee A. A. F. and several other posts where large numbers of Negroes are stationed. Several of these programs were organized and carried out by superior Negro medical officers, backed by strong command support and utilizing all available control procedures, including suppression of prostitution, educational mediums, recreational facilities, religious appeals, competitions, and the training and development of Negro noncommissioned venereal disease control officers responsible for venereal disease control in their units. These local programs have demonstrated the value of employing specially trained Negro personnel, both medical and lay, and the need for a direct and personalized approach.

CONCLUSIONS

The postwar period will present far greater assets for the control of the venereal diseases than have been available at any previous time, some of which are as follows:

1. A tremendous number of physicians and lay personnel trained and experienced by the Army in the principles of venereal disease control will be available.

2. The dilution of the postwar population by 9,000,000 soldiers will raise the general venereal disease educational level to a new high, and it seems certain that future venereal disease control programs will be accorded increased public support. In this connection, efforts to reimpose a blackout on the venereal diseases are doomed to failure.

3. The remarkable advances in treatment climaxed by the introduction of penicillin will add great impetus toward achieving the goal of universal case finding and case holding.

4. Mass wartime experiences will add considerably to the venereal disease control armamentarium.

These factors, added to the stabilization of community life and the return of opportunity to follow the natural instincts of monogamous relationships, all lead to the conclusion that we shall be presented with an unprecedented opportunity to reduce the incidence of the venereal diseases to a manageable minimum.

THE CLINICAL DIAGNOSIS, PROGNOSIS AND TREATMENT OF ACUTE HEMA- TOGENOUS OSTEOMYELITIS

FRANK D. DICKSON, M.D.

KANSAS CITY, MO.

The title clearly defines the scope of this paper. Etiology will not be discussed; the pathologic changes occurring in bone as revealed by the x-rays have been described by Pierson and Roach.¹ It is necessary, however, in order to lay the groundwork for a discussion of the clinical diagnosis and treatment of acute hematogenous osteomyelitis that certain basic features of its etiology and pathology be commented on. The facts presented are based on the study of 295 cases of the disease treated over the period of the last fifteen years.

Hematogenous osteomyelitis is a pyogenic bone infection. The staphylococcus is the offending organism in approximately 90 per cent of all cases, usually the hemolytic *Staphylococcus aureus*. The next most common organism found in culture is the streptococcus; occasionally a pneumococcus is found. While the staphylococcus is the organism found in 90 per cent of cases as a whole, in children under 2 years of age, the streptococcus is far more frequently the infecting organism—from 40 to 50 per cent. The higher incidence of streptococcal infection in very young children is probably to be explained on the basis of the antecedent source (upper respiratory tract) and the fact that the infant has relatively less natural immunity to strains of streptococci than to staphylococci, as shown by the investigations of Green and Shannon.^{2a}

According to our present understanding of the disease the focus of infection in bone is secondary to a primary focus elsewhere in the body, the pathway of infection being the blood stream; at least no valid reason has been advanced to disprove this view. To meet this accepted basic conception of the origin of osteomyelitis it is necessary to assume that there occurs a bacteremia, produced by a shower of bacteria entering the blood stream from a primary focus of infection already present. Once such a bacteremia occurs, clinically it may

follow one of three courses: (1) The organism in the blood stream may be rendered harmless by the defensive mechanisms of the body and no general or local disease develops, (2) some of the bacteria may lodge in bone, localize and set up an osteomyelitis or (3) the bacteremia may become a septicemia, which in turn results in a pyemia with abscess formation over widespread areas, including the lungs, kidneys, spleen, liver and bone. When the second of these possibilities develops, the bacteremia disappears, usually within twenty-four to forty-eight hours, leaving behind only the local bone abscess and such systemic reaction as may arise from the local pyogenic infection in the bone. When the third course is followed, a blood stream infection persists and a pyemia develops.

When bacteria find their way to the bone and become localized there, a destructive process is set up. The area of bone infection occurs with remarkable consistency in the metaphyseal region of the long bones. The generally accepted reasons for this localization are that the area has a rather large and stagnant blood supply, is an area of rapid growth and is subject in growing children to direct and indirect trauma. These reasons on the whole fail satisfactorily to explain completely the cause for fixation of the abscess in this area. Fraser² offers a suggestion which is certainly worthy of consideration and investigation. He holds that the reticuloendothelial tissue, which is present in abundance in the metaphyseal area of growing bone, is a factor in determining the frequent localization of infection in this area. He reasons that, since one of the important functions of the reticuloendothelial system is that of acting as a defense mechanism against infection, the localization or fixation of the infection in the metaphysis is the result of the defense activities of the reticuloendothelial cells in this area in their efforts to correct a general infection. On such a basis the occurrence of a localized or fixation abscess, while it creates a regrettable and difficult situation as far as the bone is concerned, should be looked on as a providential occurrence, for it is nature's method of producing a defense area from which the factors of immunity are organized and developed. Wilensky's³ point of view is different from the one which holds that the metaphysis is the usual fixation point for abscess formation, and he notes other points which are more frequently involved.

Once bacteria have lodged in the bone, wherever the fixation point may be, they multiply and liberate exotoxins which diffuse into surrounding bone, destroy and break down red cells, coagulate plasma and cause the death of leukocytes. Since this process occurs in tissue which is dense and hard and lacks the elasticity of soft tissue, it disperses rapidly. There occurs extensive thrombosis of vessels, and so there is less opportunity for the defense cells of the organism to wander into the inflammatory region to overcome infection and aid the connective tissue cells in walling off the area. Leukocytes appear in large numbers, but they are fighting a losing battle against the exotoxins and are destroyed, and a proteolytic ferment is liberated which autolyzes or destroys the dead bone and an abscess is formed. The pathologic changes in bone which result are many and varied, but any description of these changes will be omitted here, as they were discussed by Pierson and Roach in their presentation.

Read before the joint meeting of the Section on Orthopedic Surgery and the Section on Radiology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

CLINICAL PICTURE

The clinical picture about to be presented is not in complete conformity with views widely held. It is, however, a concept of hematogenous osteomyelitis which seems to fit the situation as it has presented itself in our clinic over the period of the last twenty-five years.

The patient with acute hematogenous osteomyelitis is usually a child or an adolescent, although osteomyelitis does occur in the adult. There may be a history of an already existing infection, such as a boil or furuncle, upper respiratory infection or middle ear disease. A history of trauma is elicited in from 25 to 40 per cent of the cases. With this background, although the disease varies greatly in severity, it is usually possible to differentiate two types of onset and, I believe, two types of the disease, based on the mode of onset and the clinical cause. At least the character of the onset of symptoms should be definitely suggestive.

In the usual case the first symptoms are pain and stiffness in the affected region—sometimes in the upper but more frequently the lower extremity. There is disinclination to move the extremity, and it is carefully guarded against jarring. Pain gradually increases in intensity, temperature rises and a mild chill may occur. At this time the limb is usually held in a position of slight flexion of the joint nearest which the infection is located. Flexion of the joint may be permitted without protest, but extension of the joint is always painful and resisted. This finding is a definitely important differential diagnostic fact. The temperature rises rather rapidly to 102-104 F. with a proportionate increase in the pulse rate to 120-130 per minute. The skin becomes hot and dry, the face flushed, the tongue coated and the urine concentrated. In from a few hours to three days the pain in the affected region becomes intense, and the patient will not permit the limb to be moved or even touched without protest. Restlessness and exhaustion due to toxemia develop. With continued high temperature there is a decrease in the intake of fluids, and signs of dehydration appear.

Locally there is definite tenderness to palpation over the involved area, usually the metaphyseal region if a long bone is the site of infection. This area of tenderness to palpation, sharply localized, makes its appearance early in the disease and before local swelling, redness and warmth are evident. A careful, gentle, patient investigation with the tip of one finger will usually localize the tender point, which should be most carefully sought for, since it is the most important early diagnostic sign of osteomyelitis. Later the affected region becomes swollen, red, hot and edematous, and the pain and tenderness become more diffuse. Fluctuation does not as a rule appear until the bone abscess has ruptured through the periosteum and pus has escaped into the surrounding soft parts.

Such a clinical picture with evidence of general toxemia and definite signs pointing toward a localized bone abscess is typical of the usual form of hematogenous osteomyelitis. The patient is ill, sometimes seriously so, but the outstanding feature of the illness is evidence of a localized infection in one bone, rarely more.

The second type of onset differs from that described and should suggest, I believe, a different form of the disease. The onset is usually abrupt and is initiated with a chill, although there may be a prodromal period of one to two days during which time the patient complains of not feeling well, is listless and has no appetite.

After the chill there is a rapid rise of temperature, the pulse becomes accelerated and running, the patient is restless and exhausted, dehydration quickly develops and delirium is not infrequent. The patient is seriously ill and gives evidence of an overwhelming toxemia. There may be localizing signs of pain and tenderness in the upper or lower extremity, but these are not outstanding and may be absent or masked by the serious systemic reaction. Patients presenting such severe constitutional symptoms with few or no localizing symptoms are in all probability suffering from a septicemia which is the real disease. If the septicemia persists there follows a pyemia with abscess formation in various organs and tissues of the body, including bone. That this condition should be called an osteomyelitis is, I feel, decidedly questionable, since such abscesses as may occur in bone, usually not single but multiple abscesses, seem to be incidental to the septicemia and pyemia—in other words, they are only part of the general picture of multiple abscess formation. This type of osteomyelitis has been called the fulminating form; it is resistant to all efforts at control and frequently ends fatally.

LABORATORY FINDINGS

The blood picture in acute hematogenous osteomyelitis depends on the duration and severity of the infection. As a rule in the ordinary case there is a leukocytosis of from 15,000 to 25,000 per cubic millimeter. With severe and overwhelming infection there may be little or no increase in the leukocyte count. Failure in leukocytic response is a grave sign, for it suggests that the patient's resistance is low and the effects of the infection overcome the defense mechanisms which case the prognosis is grave. The differential count usually shows a pre-dominance of polymorphonuclear leukocytes.

Early in the disease the red blood cells show little effect, but as the disease progresses anemia develops, probably as the result of the destruction of red cells by the toxins liberated.

Blood cultures are important both in indicating the form of the infection and in determining the presence of a septicemia. A blood culture should be made on all suspected patients on admission to the hospital and should be repeated at intervals. In the type in which a bacteremia occurs and a localized bone abscess develops early the blood culture may be and frequently is negative. A positive blood culture persistently present indicates a true septicemia, and the outlook is extremely grave.

The antitoxic titer level is important in estimating the natural defense against the toxigenic staphylococci. The antitoxic titer of individuals varies considerably, some having a definitely lower titer than others; adults have a higher titer normally than infants and children. A low titer signifies a low natural resistance to the staphylococcal toxin and indicates that the natural defense mechanisms cannot be relied on to be of much assistance in combating the infection. It is an interesting fact that the titer in chronic osteomyelitis is invariably quite high.

DIAGNOSIS

In children in the age group of from 3 to 15 years any acute illness characterized by a sudden onset, high temperature, pain over a bone in the vicinity of a joint and a high leukocyte count should strongly suggest hematogenous osteomyelitis and a careful examination for local tenderness over a bone end should be carried

out. It is difficult to understand the frequency with which this condition is overlooked, since its incidence is moderately frequent and its distribution wide. The outstanding diagnostic finding is localized tenderness over the bone, usually a long bone, and most commonly over the metaphysis. This localized area of tenderness can usually be disclosed by a patient, gentle and searching examination.

The condition which most closely resembles osteomyelitis is pyarthrosis; the evident enlargement about the joint with the swelling confined to the outlines of the synovial pouch, limitation of motion in the joint in all directions—not merely in extension—and the less toxic early course of the disease should make it possible to differentiate between these two conditions.

Cellulitis is frequently mistaken for osteomyelitis, as its onset is similar; that is, with chills and fever. In cellulitis, however, the redness and edema appear very early; in fact, coincident with the systemic reaction, the tenderness is over the entire area of involvement, not definitely localized, the pain is much less and of a different character and the toxemia not nearly so pronounced.

Aside from these two conditions there should be little difficulty in making a diagnosis of osteomyelitis if a careful examination is made and the patient's general condition evaluated. The facts are, however, that in a very high percentage of cases osteomyelitis goes undiagnosed for days and even weeks and until extensive bone destruction has taken place. Rheumatism was the diagnosis most frequently made in these neglected cases in the past; but fortunately today, except in isolated communities, the profession has awakened to the possibility of bone infection, and an earlier diagnosis is being made with greater frequency.

PROGNOSIS

The prognosis in acute hematogenous osteomyelitis depends on whether the case is one in which there is a transient bacteremia with the formation of a local bone abscess or whether it is one in which a true septicemia is present with pyemia. In the former the prognosis as to recovery is good; in the latter it is grave, and a fatal outcome is a frequent result. Because these two types have never been separated in statistical studies, figures on the mortality rate in osteomyelitis vary widely from 2 per cent up to 30 per cent. Obviously, with such wide variation in figures, quite different types of cases are being dealt with. In the series presented there were 38 cases of acute osteomyelitis with a mortality rate of 11.2 per cent. All but 2 of the fatal cases in this group were the fulminating form with septicemia and positive blood cultures. The average mortality, as nearly as can be determined in the usual type of the disease, is somewhere around 10 to 15 per cent. The mortality in the septicemic type is well over 50 per cent—perhaps higher. There is great hope, however, that with the advent of the sulfonamides and penicillin the mortality rate in the fulminating type will be materially decreased. The mortality rate in infants is high. Green and Shannon¹ report a general mortality rate of 21 per cent, with a rate of 45 per cent in those under 6 months of age.

The prognosis, so far as healing of the local bone focus is concerned, is poor. A great majority of the patients 3 years of age or older pass on to the chronic stage; in infants, however, there is little tendency for the disease to become chronic. The difference in the

behavior of bone in extremely young children compared with older children and adults has been considered to be due to three factors: (1) The infection in young children is frequently a streptococcus, which causes less bone destruction than does the staphylococcus; (2) the large cancellous spaces in the infant allow the infection to pass more readily from the site of the origin into the subperiosteal space, and the periosteum, being loosely attached in the infant, separates readily or ruptures, thus affording early drainage for the infection and insuring minimal bone destruction; (3) dead bone in young children absorbs very quickly, and new bone formation is rapid. The tendency to chronicity in older patients is largely due to inadequate treatment in the acute stage. It is to be hoped that a better understanding of the disease and its early treatment, combined with the use of the sulfonamides and eventually penicillin, will change this picture to a much more favorable one.

TREATMENT

There is at the present time considerable divergence of opinion as to the proper procedure to follow in the treatment of acute hematogenous osteomyelitis. The differences of opinion which exist over the type of treatment to be followed could speedily be harmonized, I believe, if it was recognized from the beginning that acute hematogenous osteomyelitis can as a rule be separated into that type in which the constitutional symptoms are comparatively mild, while the signs of local infection in the bone are definite and outstanding; and a second type in which the constitutional symptoms are severe and overwhelming, while the local symptoms of abscess formation are absent or masked by general symptoms. In the first type the picture is that of local infection, associated with which are the constitutional symptoms concomitant with a localized infection. In the second type the picture is that of a systemic infection, a septicemia, as a consequence of which a pyemia develops with multiple abscess formation in bone and other tissues. The basic pathologic condition and clinical course of these two types are entirely different, I believe, and consequently each demands a different kind of treatment.

In discussing the treatment of the acute stage of hematogenous osteomyelitis, the cases should be divided into two groups: group 1, infants—that is, children under 2 years of age; group 2, children over 2 years of age, adolescents and adults.

The treatment of osteomyelitis in infants should be conservative. The different reaction to infection which bones in infants display as compared with mature bones has been discussed under prognosis; it is this difference in behavior which makes conservative treatment so successful in infants. The care of the patient rather than the osteomyelitis is the important consideration. Supportive treatment, prevention of dehydration and immobilization of the affected extremity are the essentials of management.

Antistaphylococcus serum should be administered if the infection is due to the staphylococcus and if the serum is available.

The unquestioned bacteriostatic effect of the sulfonamides and penicillin should be taken advantage of. All information indicates that the sulfonamides are of definite value in controlling the disease. It seems highly probable from the present available reports that penicillin therapy will prove even more effective than the sulfonamides.

Locally the treatment should be conservative. As a rule the delicate periosteum ruptures early and pus escapes into the surrounding soft parts. When this occurs, simple aspiration through a large needle will usually take care of the situation. If it does not, the abscess should be drained. If temperature elevation and pain persist, the subperiosteal abscess probably has not ruptured and an incision down to and opening the periosteum should be made. A small opening into the bone may be made at this time if it seems advisable. Unquestionably the less surgery used in treating infants, the better is the outcome. Sequestration in infants is rare, and if it does occur it should be taken care of at a later date.

The treatment of the acute stage of osteomyelitis in children over 2 years of age, adolescents and adults is not the comparatively simple problem that it is in infants. The less favorable histologic and anatomic structure of the more mature bone makes it more vulnerable to attack by the pathogenic organisms and provides less effective and rapid drainage for pus into the subperiosteal space. Consequently more pronounced toxemia is present, more bone destruction takes place and there is a definite tendency for the acute condition to pass over into the subacute or chronic stage. In this group treatment should be carried out along several lines—general supportive measures, chemotherapy, administration of staphylococcus antitoxin and management of the local bone disease.

General treatment is very important, since the toxemia and dehydration are frequently pronounced. Relief of pain by morphine or codeine and immobilization of the affected part are imperative. Dehydration is combated with fluids by mouth or intravenous administration of saline-glucose solution. If the patient is definitely toxic and the blood count shows definite anemia or low hemoglobin, a transfusion of from 400 to 500 cc. of blood should be given, depending on the age of the individual.

Chemotherapy.—The accepted bacteriostatic effects of the sulfonamides make them a potent agent in combating infection in osteomyelitis. Since the staphylococcus is the infecting organism in about 90 per cent of the cases of hematogenous osteomyelitis, sulfathiazole is the drug which should be used; it is the most effective of the sulfonamide group for staphylococcal infection—at least the most effective of any produced up to the present time.

Staphylococcal antitoxin has not been very widely used, although at the present time highly concentrated and purified serum is available. Investigators, notably Shands and Baker,⁴ report excellent results with its use. These authors report a reduction of mortality from 70 per cent in 30 cases in which the antitoxin was not used to a mortality of 25.7 per cent in 35 cases in which it was used. The high mortality rate reported by Shands and Baker would indicate that they were dealing in their series with a staphylococcal septicemia with profound intoxication. The few cases in the series reported in which antitoxin was used were of this type, and its administration failed unfortunately to alter the course of the disease and save the patient's life.

The use of penicillin seems to give promise of being a most potent adjunct to the treatment from the few reports at hand. Unfortunately, penicillin has not been available for clinical research, and no definite statement can be made as to its effectiveness at this time.

Specific agents to control infection at the present time have not established themselves in a positive position. Toxoids which increase the immunity of the patient are too slow to be helpful; it requires about two weeks before effective immunity can be established. Bacteriophage is still on trial.

Local Treatment.—There is some difference of opinion today over the proper treatment of the local bone focus. The chief controversy is over the question of drainage; that is, whether the focus should be drained or should not be drained. This controversy has become so heated that it seems likely to confuse the whole problem of treatment to a disastrous extent. It seems worth while, therefore, to attempt to place this question of drainage on a rational basis with the hope that some good may come of it. There are two distinct schools of thought on this point: those who consider osteomyelitis an acute surgical emergency which demands drainage at the earliest moment consistent with safety and those who maintain that drainage is contraindicated and detrimental. The advent of the sulfonamides and penicillin with their bacteriostatic effects has added fuel to the flames of this controversy. Those who advocate nonin

nonin (1) t of antibacterial influences which are effective in combating the general infection and, therefore, it should not be disturbed, and (2) the belief that the natural defense mechanisms of the body will take care of the systemic and local infection. Those who advocate early drainage maintain (1) that the problem is a surgical one and is not entirely one of immunology, that the general resistance of the patient cannot be expected to increase rapidly enough to combat successfully the local and general infection, and (2) that the undrained local infection in bone tends to spread and to destroy more and more bone and, therefore, surgical drainage is necessary and should be carried out at the earliest moment consistent with sound surgical judgment. While individual opinion based on experience may be for or against drainage of the bone focus, one fact seems fundamental and should be generally accepted. This is that a localized bone abscess, which is the usual type of osteomyelitis, is one thing, and a septicemia with multiple abscess formation is another. When dealing with a localized bone abscess, surgical drainage is a sound surgical procedure. When dealing with a septicemia with inconclusive signs of localized abscess formation in bone or with signs of multiple abscess formation, surgery has no place in treatment and may possibly accelerate a fatal termination. From a careful study of a wealth of material and reports, it seems probable that this differentiation has not always been made, and many patients with septicemia have been operated on who should never have been subjected to surgery. This has led many to conclude that surgical drainage is unwise and harmful—a faulty conclusion which would be rectified to a large extent, I believe, by a more careful segregation of cases by type in statistical records.

In view of the fact that it is an established surgical principle that a focus of infection with tissue destruction must be drained, it does not seem logical to depart from this principle when dealing with an abscess in bone. Bone is a tissue which, when infected, has little defense and poor recuperative power except in infants and for this reason would seem to demand drainage even more urgently than an abscess of the soft parts in order to relieve the general toxemia, reduce to a minimum the

4. Baker, L. D., and Shands, A. R., Jr.: Acute Osteomyelitis with Staphylococemia, J. A. M. A. 113: 2119-2124 (Dec. 9) 1939.

amount of bone destruction and lessen the danger of reinfecting the blood stream with the probable development of metastatic abscesses. On this basis, my position in treatment has been drainage of the local bone abscess at the earliest moment; that is, at the earliest moment that the patient's general condition will permit, except in those cases in which the acute onset with a chill, the grave constitutional symptoms and lack of signs of a definite bone localization indicate a septicemia.

The time selected for drainage is determined by the patient's general condition. If this is relatively good and dehydration has not set in, immediate operation may safely be performed. If there is evidence of grave toxemia and dehydration, the operation should be delayed until rest, the administration of saline-glucose solution and blood transfusions convert a poor surgical risk into a safe one; this may be a matter of twenty-four hours or a week or more. In the meantime, blood cultures should be made frequently to determine whether a septicemia is present and, if so, its course.

When the decision to drain has been reached, drainage should be thoroughly established but with a minimum of surgery. An adequate incision should be made in the soft parts over the point of greatest tenderness and, following muscle planes as far as possible, carried down to the bone, which should be thoroughly exposed. Ordinarily, a window about 1 inch square should be removed from the cortex of the bone with an osteotome for adequate drainage. If haste is desirable, one or two drill holes may be substituted for window drainage. Incising the periosteum without opening the cortex of the bone does not provide adequate drainage. The wound should be lightly packed with petrolatum gauze or gauze soaked with diluted solution of sodium hypochlorite. I prefer the latter. The extremity is then immobilized in plaster or, if the patient is quite ill, by traction or sandbags.

In a fair percentage of cases with early drainage and the administration of the sulfonamides, extensive necrosis of bone will not occur, and the wound under careful aseptic dressings (Dakin's irrigation or packing with sterile petrolatum gauze) will heal by granulation. Twenty-nine out of 33 cases of acute hematogenous osteomyelitis in this series had early drainage and Carrell-Dakin treatment. Seven, or 28.5 per cent, healed without additional surgery. Only 5 of these 7 cases were treated after the introduction of the sulfonamides. Penberthy and Weller⁵ report 19 cases treated by early drainage and the systemic administration of sulfathiazole. Of these, only 2 had later sequestration and required additional operation.

It is only fair to state that today there is a definite trend against early drainage of the localized bone abscess in hematogenous osteomyelitis. This position has received additional impetus with the introduction of the sulfonamides. The bacteriostatic effects which the sulfonamide drugs exert seem unquestionably to bring about the disappearance of the constitutional symptoms and control the local bone infection in some but not in all cases. These drugs, however, can have no effect on the local bone destruction which has occurred before the infection was brought under control, and the necrotic tissue which results remains as a possibly quiescent but certainly unhealed focus in the bone. As long as the x-rays reveal definite areas of bone destruction

and sequestrum formation, no matter how silent the area may be clinically, the case cannot be spoken of as cured but only as one which shows a clinical recession with a quiescent bone focus. Such quiescent areas may remain dormant for years and in some cases permanently. However, an examination of a number of cases treated by the administration of the sulfonamides without drainage has shown that in practically all a careful x-ray examination revealed persistent areas of bone destruction which are readily differentiated from the surrounding normal bone. Such areas constitute potential sources of trouble in the future. Wilson and McKeever⁶ report 3 cases treated by administration of the sulfonamides without drainage with subsidence of acute symptoms, in which several months later drainage was established because of persistent local induration. Thick, soft, hyperplastic bone was encountered and granulation tissue was found in the medullary canal when drainage was established. Smears and cultures revealed staphylococci. These findings clearly indicate that such quiescent foci are not really sterile but that they probably harbor dormant bacteria capable of activity.

Treating a bone abscess with the sulfonamides and without drainage may result in putting out the fire; but the ashes remain, and only too frequently ashes which have embers likely to be fanned into activity by such breezes as lowered resistance or local trauma to the quiescent area. My observations have convinced me that sooner or later a large percentage of these quiescent foci do become active. Whether penicillin proves to be an agent which, more powerful than the sulfonamides, will completely sterilize such areas of infection only time will tell. Until then the preponderance of evidence is in favor of early drainage of the osseous focus in acute hematogenous osteomyelitis except in the fulminating type with septicemia and pyemia, when the drainage of a single focus, where there are probably others present, cannot be expected to have any helpful effect but will probably do harm.

1103 Grand Avenue.

ABSTRACT OF DISCUSSION

DR. HOWARD HATCHER, Chicago: In children osteomyelitis is primary in a metaphysis and not in an epiphysis. That is true of both pyogenic and tuberculous infection. It is a rare case that shows evidence of primary infection of an epiphysis. In adults, however, osteomyelitis or other infection may start in epiphyseal bone. Acute osteomyelitis does not alter the bone structure for several days. The ideal time for treatment is before there has been alteration sufficient to produce changes in the roentgenogram. Usually, however, by the time the patient undergoes treatment areas of bone absorption are seen in the metaphysis. These areas of rarefaction in acute osteomyelitis do not denote the extent of the disease. They represent only the initial lesion, and extension through the shaft may have occurred by the time the bone is opened. The fate of bone in osteomyelitis depends on the age of the patient, the virulence of the infection and to some extent on treatment. It has been mentioned that in infancy bone may be killed and rapidly absorbed. Even sequestrums in infants may be absorbed without the necessity of surgical removal. The extent of necrosis of bone cannot always be determined from early roentgenograms. Sometimes necrotic bone in the presence of an organism of low virulence does not become separated and may undergo replacement by living bone. In virulent infection dead bone, particularly in the cortex of the shaft, separates

5. Penberthy, G. C., and Weller, C. N.: Chemotherapy as an Aid in the Management of Acute Osteomyelitis, Tr. South. S. A. 53: 391-408, 1940.

6. Wilson, J. C., and McKeever, F. M.: Hematogenous Acute Osteomyelitis in Children, J. Bone & Joint Surg. 18: 328-352 (April) 1935.

and the overlying periosteum may or may not form new bone. If periosteum is killed by the infection, it fails to form an involucrum, and pathologic fracture may be the result. Another point to be considered is the fact that periosteal ossification occurs also in diseases other than osteomyelitis. It should be emphasized that periosteal new bone formation with raylike vertical striations is not pathognomonic of tumor. The onion skin appearance oftentimes cited as being typical of Ewing's tumor may be seen also in osteomyelitis. Roentgenology of bone is an interpretation of the pathologic changes within that bone. If specific terms are employed, calcification and ossification cannot be used interchangeably. Calcification implies deposition of lime salts such as is seen in necrotic tissue. Ossification, it is true, ultimately involves calcification, but only in the process of new bone formation.

DR. E. E. MANSUR, Jefferson City, Mo.: A man aged 32, with a chronic osteomyelitis of the humerus in the metaphysal area characterized by great pain and limitation of motion of the shoulder was treated with sulfonamides and general tonics over a period of six weeks, with no relief. Later it was thought that he might have a secondary infection with Vincent's disease from a primary infection found about his teeth. Since 50 per cent of all of us harbor Vincent organisms in our mouths, I think we shall see more and more of it, because dentists are not taking an active interest in Vincent's disease. This man having been treated in the usual orthodox manner with heat, massage, restoratives and sulfonamides, without any benefit, was given neoarsphenamine with dramatic effect. Within twenty-four hours his pain had been relieved far more than any other therapeutic measures had accomplished. He was given weekly injections. At the end of a month he was completely well, although the bone changes had not been great, as shown by subsequent roentgenograms. His reaction to arsphenamine, given because of definite dental Vincent's infection, with failure of all other forms of therapy and occurring almost overnight, suggests that Vincent's spirillum is perhaps one of the causative organisms of osteomyelitis. The x-ray changes were those of a periostitis. The case was followed for three months, when after its incipient stage subsequent films showed perforation of the cortex; but the changes were not those seen in syphilis of the bone. This patient had a negative Kahn reaction.

DR. CARL E. BADGLEY, Ann Arbor, Mich.: I was quite impressed by Ward McNeil's demonstration of the effectiveness of his bacteriophage. I have been impressed with the efficacy of Ward McNeil's synthetic bacteriophage in the treatment of staphylococcal infections. In 13 septicemias there were 12 survivors, one of the lowest death rates by any form of treatment. In our clinic we did just as Penberthy and Wal-lard did, and treated our patients by the usual surgical procedures plus oral sulfonamide. Second, we tried oral sulfonamides alone and were dissatisfied. Third, we tried oral sulfonamide and drainage of abscess in soft tissue only. Fourth, we tried the procedure which is my thesis, that one can improve the possibility of cure of this condition by early operation, by drainage of the metaphysal area, by implantation locally of the sulfonamide or penicillin in addition to the oral method. From the good results in chronic osteomyelitis we felt we might close the wound after draining the bone, and we have primarily closed the wound after we have instilled sulfonamide or penicillin into the wound. We have then closed it and have had excellent results, with the exception of 1 case in which it was necessary to open and drain further.

DR. FRANK D. DICKSON, Kansas City, Mo.: Two cases of osteomyelitis treated with systemic medication (sulfonamides and penicillin) but with no local drainage showed extensive bone destruction and still active bone foci after eight weeks and several months, respectively, from the date of onset. The third case, which was treated by the systemic administration of the sulfonamides and local drainage, showed a minimum bone destruction and complete healing within nine weeks of the onset. The importance and necessity of early drainage in acute hematogenous osteomyelitis with localized bone abscess is thus suggested.

Clinical Notes, Suggestions and New Instruments

INTRAVENTRICULAR PENICILLIN

A NOTE OF WARNING

HERBERT C. JOHNSON, M.D., and A. EARL WALKER, M.D.
CHICAGO

The intraventricular use of penicillin has been suggested for cases of meningitis which do not respond to the parenteral or intrathecal modes¹ of administration. Since reports of penicillin given in this manner are rare, it seems pertinent to present the following case, which emphasizes certain reactions to the intraventricular injection of the drug:

D. K., a boy aged 22 months, was admitted to Bobs Roberts Hospital on April 25, 1944. His parents stated that for the previous two months they had noticed that the child was becoming increasingly irritable. Two weeks before admission the patient had vomited four to six times over a period of three days. About the same time they had noticed that he was unable to turn his left eye outward. Birth, developmental and family histories were noncontributory to the present illness.

Physical examination at the time of admission revealed that the child was well developed and well nourished and was not in acute distress. The physical examination, except for the neurologic findings, was normal. His head was obviously enlarged, measuring 52 cm. in occipitofrontal circumference. The scalp veins were prominent over the temples. Macewen's sign was strongly positive. There were 3 diopters of papilledema bilaterally and a left abducens palsy. The tendon reflexes were slightly hyperactive, and the plantar responses were bilaterally extensor. The neurologic examination was not otherwise abnormal.

Laboratory examination showed a red blood cell count of 5,350,000, a white blood cell count of 17,450 and a hemoglobin of 12.5 Gm. The sedimentation rate was 42 mm. per hour. Differential count and urinalysis were normal. The Wassermann test on the blood was negative. Cultures of the nose and throat grew no pathogenic organisms.

The patient's temperature at the time of admission was 37.8 C. (100 F.). Three days later the temperature was 39 C. (102.2 F.) and it was found that the child had a left otitis media. A left myringotomy was performed, obtaining a small amount of thin pus, culture of which was sterile. The patient was given 0.5 Gm. of sulfadiazine every four hours.

Roentgenologic examination revealed a normal chest and normal mastoid air cells. There was no radiologic evidence of a lead line in the wrist. Roentgenograms of the skull showed diastasis of the sutures. An electroencephalogram showed increased electrical activity ranging from about 1 to 11 per second. There was no localization of the abnormal activity.

The clinical impression was that the child was suffering from internal hydrocephalus. It was thought that the most likely etiologic factor was a medulloblastoma of the cerebellar vermis. By May 4 the otitis media had cleared and the child's temperature was normal. Because of the patient's age, it was deemed advisable to do a decompressive procedure followed by x-ray therapy rather than a suboccipital craniectomy.

Accordingly, on May 4, with the child under ether anesthesia, bilateral perforations were made in the posterior parietal regions. No subdural hematoma was found, and exploration with the brain puncture needle encountered no abscess nor unusual resistance. The right lateral ventricle was then tapped, and 5 to 10 cc. of clear fluid escaped. There did not appear to be much tension within the ventricular system, and there was only a moderate increase in ventricular fluid. A catheter was then inserted through the tract of the brain puncture needle and left in the ventricle. To the external end of this catheter had been tied a condom. The wounds were then closed.

The day following operation, x-ray therapy was started. During the succeeding eleven days the patient received about 750 roentgens (depth dose), a posterior port and two lateral

ports being used. Beginning on the day of operation ventricular fluid was aspirated from the condom at periodic intervals as indicated in the table. During the first postoperative week the patient did very well. The temperature remained normal and the child was eating well, seemed cheerful and in no distress. Sulfadiazine, which had been stopped on the day of operation, was given again in doses of 0.5 Gm. every four hours on May 7. On May 11 the temperature reached 39.4 C. (102.9 F.) and on the following morning the aspirated fluid was faintly cloudy. Cultures of this fluid were sterile, but fluid aspirated two days later contained *Staphylococcus albus*. Since the administration of sulfadiazine (the blood level of which varied between 11.2 and 17.5 mg. per hundred cubic centimeters) did not appear to be controlling the infection, it was decided to give the patient penicillin.

In spite of the elevated temperature, the child did not appear ill and seemed to be in excellent condition. On May 15 the patient was given 100,000 Oxford units of penicillin in six intramuscular doses (10,000 units per cubic centimeter of isotonic solution of sodium chloride). On May 16 it was decided to administer the penicillin intraventricularly through the catheter. On this day at 4 p. m. 50,000 Oxford units of penicillin was given intraventricularly in 5 cc. of isotonic solution of sodium chloride. At 5 o'clock the child was found unconscious in a state of collapse. The blood pressure was unobtainable and the pulse was faint and thready. The skin was cold and ashen. There was pronounced stiffness of the neck. The extremities were flaccid, and the tendon reflexes were absent.

Laboratory and Clinical Observations

Ventricular Fluid							
May 1944	Leukocytes		Protein, Mg. per 100 Cc.	Culture	Intra-ventricular Penicillin (1,000's Units)	White Blood Cells (1,000's)	Highest Temperature, C.
	Total	Percentage Polymorpho-nuclear					
4	127	0	35	14.5	39.2
5	900	5.0	44	39.6
6	125	...	47.5	39.0
12	Negative	...	9.2	38.6

22	206	38.0	103.3	Negative	30	4.4	39.0
23	6.7	37.6

The condom was removed from the catheter to allow free drainage of ventricular fluid, and a hypodermoclysis of 500 cc. of isotonic solution of sodium chloride was started. After fifteen to twenty minutes the patient began to move his eyes slightly and to respond faintly to painful stimuli.

At 7 p. m. the patient had a generalized convulsion lasting several minutes. One grain (0.06 Gm.) of phenobarbital sodium was given intravenously and 2 grains (0.13 Gm.) subcutaneously. During the course of the next hour the patient had frequent paroxysmal generalized clonic spasms of the arms, legs and neck. About midnight he began to respond and by morning was sitting up in bed playing with his toys. On May 17 the ventricular catheter slipped out when the dressing was changed. During the next two days, May 17 and 18, the temperature was normal and no penicillin was given. On May 19 the temperature rose to 39.8 C. (103.6 F.). The patient did not, however, appear ill. At 10:30 a. m. he was given 15,000 Oxford units of penicillin in 3 cc. of isotonic solution of sodium chloride through a ventricular puncture needle introduced into the right lateral ventricle. Four hours later the patient was conscious and responsive but was having frequent twitches of the right arm and leg. These lasted for several hours. At 6 p. m. that day another 15,000 Oxford units of penicillin was given intraventricularly. The patient had been started on phenobarbital 0.06 Gm. twice a day on May 17, and no further convulsive movements were seen after May 19. For the following three days, May 20, 21 and 22, the child was given 15,000 units of penicillin intraventricularly each morning and each evening.

The patient gradually began to improve. Within a week his temperature subsided to normal values. On June 7, 1944 the

patient was discharged. At that time he was up and walking with a normal gait. There was a very minimal papilledema of the nasal margin of both disks. External ocular movements were normal. The tendon reflexes were intact, and motor power was good.

On July 31 the patient was seen again in the outpatient department. Although he had had no further roentgen therapy, he had been quite well since discharge from the hospital. His right optic disk was normal. External ocular movements were full. He presented no abnormalities on physical or neurologic examination.

COMMENT

The original disease from which this child suffered cannot be diagnosed with certainty at this time. It is possible that the internal hydrocephalus was the result of a cerebellar medulloblastoma which melted away with the roentgen therapy or equally possible that it was due to serous meningitis or arachnoiditis. The genesis of the infection in the child would appear to be due to the relatively poor ventricular drainage, so that *Staphylococcus albus*, normally found in the skin, gained access to the ventricular system. That the child had little systemic reaction to the infection except for the fever suggests that the organism was avirulent or that the child had a high degree of immunity.

At the time of the administration of the intraventricular penicillin it seemed probable that the vascular collapse and convulsive seizures were to be associated with his infection rather than with the medication. The dosage of penicillin was perhaps higher than necessary, but we had no information on this point at that time. When the infection returned after the first intraventricular injection of penicillin, a much smaller amount of penicillin was used for intraventricular injection and the child was carefully watched for ill effects. That twitches occurred in the right arm and leg would indicate that local irritation at the site of brain puncture was not responsible, because the drug was injected into the right lateral ventricle. Perhaps the convulsive manifestations were minimized by the rather large doses of phenobarbital given the child. It is interesting to note that subsequent intraventricular injections had no apparent ill effects.

Whether the injection of the drug was responsible for the reaction or merely coincidental with an exacerbation of the primary disease process may now be answered in view of further studies. A critical review of the history leads one to the conclusion that the intraventricular injection of the drug was too closely associated with the reactions to be merely coincidental. The child until the time of intraventricular injection did not appear ill but was quite active and alert. The similarity of the convulsive aspects of the reactions are noteworthy. That subsequent injections of the drug did not result in ill effects does not eliminate the possibility that the drug was responsible for the first two reactions. This case stimulated further experimental investigations of this hypothesis. While these studies are not yet complete, it is evident that in cats and dogs intraventricular injection of penicillin may result in convulsive seizures or death due to circulatory collapse. Moreover, electroencephalograms of many patients receiving penicillin are distinctly abnormal. Penicillin applied to the cerebral cortex of monkeys, dogs and cats in doses as low as 500 Oxford units will induce clinical and electroencephalographic manifestations of convulsions. For these reasons we believe that the reaction in the case reported was due to the injection of the penicillin within the lateral ventricle of the cerebrum.

It seems probable that this severe reaction was due to some idiosyncrasy to the drug, because in other patients as much as 100,000 Oxford units of penicillin has been injected intraventricularly without untoward effect. That such severe reactions may occur, however, should deter one from the intraventricular use of the drug unless absolutely necessary.

SUMMARY

A patient with *Staphylococcus albus* infection of the ventricular system was treated with intraventricular injection of 50,000 Oxford units. Within an hour the patient was comatose and in vascular collapse. Supportive therapy improved the condition, but the patient had clonic spasms of the arms, legs and neck for several hours. Within a day the patient appeared normal. Two days later, when the infection became recrudescent, 15,000 Oxford units of penicillin was injected into the

right lateral ventricle. Four hours later the patient had twitchings of the right arm and leg, which disappeared in a few hours. After further intraventricular injections of penicillin without reaction the patient recovered completely. A critical analysis of the case and experimental studies on man and animals support the hypothesis that the intraventricular injection of the drug was responsible for the reactions. It is suggested that intraventricular penicillin be used in small amounts and with caution.

OCCUPATIONAL DERMATITIS CAUSED BY GERMICIDAL POWDER "MICROLENE"

ALEXANDER STERLING, M.D., PHILADELPHIA

Mrs. L. H., aged 26, a waitress, married eight years, with 1 son aged 7 years, first called at the office June 7, 1944 with a severe dermatitis of four years' duration.

She had been in good health until shortly after she changed her place of employment. She had a maculopapular eruption (areas of serous exudate covered with crustations and areas of parchment-like induration with a severe inflammatory base). The lesions began from the tips of the fingers of both hands, extending over the dorsum of the hand and the anterior and posterior surfaces of the forearm and arm, more pronounced on the flexor surfaces of both forearms, where the induration and erythema were extreme. In the last year it had also spread to the back of the neck. The rash was accompanied by severe pruritus, especially at night, and for weeks at a time the patient obtained little sleep.

While at work, whenever she entered the kitchen, fumes and steam from dishwashing machines produced pruritus on the exposed parts of her body, especially the hands and neck. The condition was unchanged in winter or summer, although it varied in intensity from time to time. The management of the firm where she was employed as a waitress referred her in the course of the four years to various skin clinics and to several dermatologists, but she obtained no relief.

The patient had had the usual childhood diseases. Otherwise the history was noncontributory. The menstrual history was normal. There was no other personal family allergy.

Laboratory examinations gave physiologic findings for blood count, blood chemistry and the urine. The Wassermann reaction was negative.

A complete allergic investigation was made. The patient was tested for foods, inhalants, pollen, bacteria, molds and dust with no positive reactions. After considerable painstaking questioning, the following outstanding facts strongly suggested that this was an occupational dermatitis:

1. Although she had been a waitress for many years, she recalled that in the first week at this new establishment she had assisted at the dish washing for a day, and her fingers and hands began to itch for a short time.

2. The induration was always more pronounced on the flexor surfaces of both forearms, this being where she carried the dishes. Although the dishes were thoroughly dried after the washing machine, I suspected that enough of the chemicals used in the washing machines remained on the dishes to produce contact dermatitis (plus moisture from the skin).

3. The fingertips and fingers remained always either split and oozing or crusted, evidently because of constant use of damp cloths to wipe the tables, which retained enough of the chemicals previously used in washing the dishes.

4. The mere presence of the patient in the kitchen during dish washing time was sufficient to produce extreme exacerbation of the existing pruritus, presumably from the steam containing the chemicals in the dishwashing machines.

5. On further investigation it was found that, in addition to soap powders, a germicidal powder called "Microlene" was used in the dishwashing machines. Patch tests were made with the soap and Microlene powders. Soap powders were negative, but the Microlene chemical produced a strongly positive reaction (plus 4).

6. The patient was advised to abstain entirely from work. Within two weeks she was completely free from any dermatitis and pruritus.

COMMENT

The germicidal chemical powder "Microlene," used in dishwashing machines of a certain chain restaurant, has a warning on the label stating that "it may produce a skin irritation in those handling it while dish washing."

I doubt that the restaurant management or the firm ever suspected that it could produce a dermatitis so severe from such presumably indirect contact as handling the dry dishes after several rinsings, or the cloth used to wipe the table on which the dry dishes were placed, or just being in the room with the vapors.

SUMMARY

A germicide used in dish washing was found responsible for a severe dermatitis and pruritus of four years' duration. The patient was a waitress who had no direct contact with the chemical. It was not recognized previously as the etiologic factor, because her contacts with this germicide were indirect and seemingly unimportant.

1737 Chestnut Street, Philadelphia 3.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report.

HOWARD A. CARTER, Secretary.

RADIOEAR, MODEL 45-M, ACCEPTABLE

(Magnetic Air Conduction Receiver)

Manufacturer: E. A. Myers & Sons, 306 Beverly Road, Mount Lebanon, Pittsburgh 16.

Model 45-M Radioear with magnetic air conduction receiver is a three vacuum tube instrument consisting of a transmitter, a magnet magnetic receiver and a battery unit.

Dimensions.—Transmitter 4 inches by 2 inches by $\frac{3}{4}$ inch. Receiver, magnetic, $\frac{3}{4}$ inch in diameter. Transmitter, receiver and cords weigh 5 ounces. Batteries weigh $1\frac{1}{2}$ ounces.

Batteries.—A battery, 1.5 volts; current drain at full volume, 79 milliamperes. B battery, 45 volts; current drain at full volume, 1.1 milliamperes.

Acoustical Gain.—Observations were made by trained observers using fitted ear molds in a tone field, within a sound proof room, seated 5 feet from a loud speaker delivering frequencies of pure sine wave characteristics. The readings are in decibel gain.

Volume Control Set at	Position of Tone Control	Frequency						
$\frac{1}{4}$	Control	256	512	1,024	1,448	2,048	2,896	4,096
$\frac{1}{2}$	Center	13	12	13	16	13	13	3
$\frac{3}{4}$	Center	15	14	23	22	20	17	6
Full	Center	18	17	26	18	23	22	8

Overall gain for speech 45 decibels.

Physical and Mechanical Features.—The instrument consists of a black plastic case of pleasing appearance. The front surface design is indented. The on and off switch, which is also the volume control, is a knurled disk placed at the top of the transmitter. A tone control at the upper right hand corner gives three distinct frequency emphases. The aid is divided into discrete sections, each of which can be replaced by a service part when servicing is needed. This can be done at the dealer's office without using a soldering iron to make the connections.

Performance.—The instrument operates in a completely satisfactory manner. There is an absolute minimum of case noise, little if any distortion at maximum intensity. Cord noise and feedback squeal are negligible. The three position tone control operated as represented.

Recommendations.—The Council on Physical Medicine voted to accept the Radioear, Model 45-M (magnetic air conduction receiver), for inclusion in its list of accepted devices.

Model 45-M Radioear

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 NORTH DEARBORN STREET - - CHICAGO 10, ILL.

Cable Address - - - "Medic, Chicago"

Subscription price - - - - Eight dollars per annum in advance

Please send in promptly notice of change of address, giving both old and new; always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, JANUARY 27, 1945

1945 DUES NOW PAYABLE

As a convenience as well as a reminder to those Fellows and subscribers who have not paid their 1945 annual dues, a colored remittance slip is enclosed in this issue of *THE JOURNAL*. These slips take the place of personal bills. If each subscriber and Fellow whose 1945 dues are not yet paid will send his remittance promptly, a vast amount of clerical work and expense will be saved. Since many physicians subscribe to *Hygeia* and to one or more of the A. M. A. special journals, the names and subscription rates of these publications are also listed on the slip. The ones desired may simply be indicated by a check mark and remittance included with the annual dues. The colored slip is cut to form an envelop when folded and does not require a postage stamp.

PENICILLIN IN WARFARE

A supplement to the July 1944 issue of the *British Journal of Surgery* presents a symposium on penicillin in warfare. In a foreword Major Gen. L. T. Poole states that employment of penicillin in the most forward surgical units as a prophylactic against wound sepsis emerges as perhaps the greatest application of the lessons learned. Under battle conditions a long interval must sometimes elapse before definitive surgical measures can be undertaken. Penicillin can be used to bridge this gap and delay, modify or even prevent the development of sepsis. Florey and Jennings point out that the substance is the most powerful antibacterial agent which has yet been brought into clinical use. Pure penicillin is likely to remain for a long time a chemical curiosity, but its antibacterial capacity is well established. It will completely inhibit the growth of

the most sensitive organisms, such as the gonococcus and staphylococcus, when diluted at least 1:50,000,000. Penicillin was shown experimentally to be bacteriostatic and not bactericidal. Its action was not significantly impaired by serum, blood, pus or tissue autolysates. In general, gram positive organisms and the gram negative cocci are sensitive and the gram negative bacilli insensitive, but some species show strain variation. The early work on penicillin showed it to be remarkably nontoxic to the body tissues.

The rapid absorption and elimination of penicillin, whether after injection or from a wound surface, suggest that relatively large doses should be given and frequently repeated. For systemic administration intramuscular or subcutaneous injection is usually used. Excretion of the drug is so rapid that probably little advantage is to be gained by increasing the single dose above 15,000 units, the size originally established as generally effective.

Lieutenant Colonel Jeffrey stresses that the treatment of battle casualties demands the intelligent combination of resuscitation, operative surgery and chemotherapy with its specific action against the common bacterial invaders of war wounds (staphylococci and clostridia in the early stages and streptococci in the later stages). Penicillin is the most effective and least harmful agent yet discovered. The drug has three main spheres in war surgery: (1) to prevent infection of the wound soon after wounding, (2) to control infection in the first two weeks and (3) to combat sepsis in the later stages. It is in the control of infection in the first two weeks, that is, at the forward base hospitals, that greatest value can be expected from penicillin. The tissues are fresh, the infection is recent, the organisms are not shut away in fibrous tissue and sequestrums, and have not become intractable and insensitive to chemotherapy. In general, systemic therapy is the method of choice in large traumatized areas that are inaccessible to local powder or solution and accessible only to the drug circulating in the blood stream. This involves most of the severe casualties, such as fractures, gas gangrene, septicemic states, amputation stumps and multiple severe flesh wounds. Lieutenant Colonel Bentley reports the results in a consecutive series of 200 casualties with flesh wounds treated by early secondary suture with local penicillin. Primary healing was obtained in 190 (95 per cent). These wounds were typical of soft tissue battle injuries, and the results show that in the presence of penicillin wound infection is controlled and that a high proportion of success follows early secondary suture. Lieutenant Colonel Brown reports much the same results. He feels that they are so good and the period of morbidity is so lessened that all soft tissue wounds, however small, should be sutured with the aid of penicillin. However, he warns that penicillin has in no way replaced and

can never be a substitute for thorough primary surgical treatment.

Furlong and Clark state that penicillin failed to control sepsis fully and did not diminish the incidence of chronic infection in open fractures of the femur. They stress, therefore, that penicillin is not a substitute for surgery and that the greatest care and attention must be given to surgical technic and to fundamental surgical principles. Jeffrey treated 33 cases of gas gangrene, with mortality of 36.4 per cent. He believes that penicillin has a definite place alongside surgery and antiserum in the treatment of gas gangrene.

D'Abreu and his associates treated 64 severe chest wounds with penicillin. They have been particularly impressed with the capacity of the pleural cavity to retain instilled sodium penicillin for as long as three days. This means that a reservoir of the best known bacteriostatic agent can be maintained at the site of infection. Conversely, passage from the blood stream into the pleural cavity is slight. The method of intrapleural instillation is thus both more economical and far more effective than that of parenteral therapy. As a prophylactic against infection, penicillin is of great value and has been used in major thoracotomy operations with satisfactory results. The authors recommend that in the forward areas the attempt to prevent infection of hemothoraces should consist in thorough aspiration combined with penicillin instillations. This would appear to offer the best hope of preventing the present high rate of hemothorax infections seen in the theater of war.

The most brilliant results with penicillin were obtained in the treatment of gonorrhea. Major Robinson of the U. S. Army reports 1,000 cases of sulfonamide resistant gonorrhea treated with penicillin, of which 94.7 per cent were free from gonorrhea after one course of treatment with 100,000 units of penicillin given intramuscularly in 10,000 unit doses every hour or in 20,000 unit doses every three hours. In this series 5.3 per cent required the second course of penicillin, varying from 100,000 to 150,000 units. Seven per cent had developed complications other than posterior urethritis. Penicillin hastened recovery in this group. There were no serious toxic reactions. Of 100 cases of acute gonorrhea previously untreated, 97 per cent responded successfully to one course of 100,000 units of penicillin and only 3 per cent required an additional 100,000 units. The author concludes that penicillin is the most effective agent for treating all types of gonorrhea. If the supply was unlimited it would be the therapy of choice.

Wise and Pillsbury of the U. S. Army confirm in general the report of Mahoney and his associates on the rapid spirocheticidal effect of penicillin in men, the prompt regression of early syphilitic lesions and the absence of significant reaction to treatment. Penicillin therapy in syphilis offers possibilities of great impor-

tance to military personnel, since prolonged treatment with arsenic and bismuth is impossible to carry out continuously under many conditions in a theater of operations. The immediate effects of penicillin therapy are superior to those observed after intensive arsenotherapy.

CONCENTRATED INFLUENZA VACCINE

In 1942 Hirst and his associates¹ of the International Health Division, Rockefeller Foundation, developed a new method of concentrating influenza vaccine from allantoic fluid infected with virus. When allantoic fluid from 13 day old infected chick embryos is frozen and thawed, a fluffy white precipitate appears. From 90 to 95 per cent of the virus is usually carried down in this precipitate. The precipitate goes back into solution when the fluid is warmed to 37 C.

While the temperature was kept at approximately 0 C. the precipitate from a large volume of infected allantoic fluid was removed by centrifugation and resuspended in one tenth the original volume of supernatant fluid. The resulting tenfold virus concentrate was then devitalized by the addition of 0.4 per cent formaldehyde solution. Equal volumes of type A and type B concentrate thus prepared were mixed and thoroughly homogenized. The homogenized mixture was distributed in ampules in 25 cc. amounts, frozen and vacuum dried.

As a test of the immunizing power of this bivalent vaccine the dried product in each ampule was dissolved in 50 cc. of warm saline solution and 2 cc. of the resulting solution injected subcutaneously into each of 100 human volunteers. Two weeks after this injection the mean antibody titer of the volunteers was higher than that previously obtained with nonviable vaccines. It was at least as high as the peak titer which follows the injection of similar amounts of living virus concentrated by centrifugation. Six to nine weeks later the antibody titer showed a pronounced drop from the two week level, with a still further drop by the end of five months.

During the last two years² the prophylactic efficiency of this concentrate has been tested in seven different penal institutions in five widely separated states. The tests were made on about 3,000 volunteers, with an equal number of nonvolunteers serving as controls. The vaccine was injected subcutaneously in 1 cc. volumes. Slight redness and swelling at the site of the injection with a moderately sore arm were common for twenty-four hours, with a mild febrile response in about 1 per cent of the cases. Titration of the serums of the vaccinated inmates two weeks later showed an average specific antibody titer five times that of the prevaccina-

2. Hirst, G. K.; Rickard, E. R., and Friedewald, W. F.: *J. Exper. Med.* 80: 265 (Oct.) 1944.

tion average of the same persons. The average titer fell to 2.5 times the prevaccination level by the end of eleven to fourteen months.

The Commission on Influenza³ found that the prophylactic effects of influenza vaccines are greatest during the second week following injection, at which time it reduces the average attack rate of influenza by about 85 per cent. The postvaccination immunity decreases in efficiency after the second week, affording but a 40 per cent reduction in the attack rate by the end of six weeks. Hirst found that the average attack rate from eleven to fourteen months later was 5.5 per cent with his nonvaccinated controls, while the rate was 3.6 per cent with the vaccinated inmates. The reduction in attack rate was therefore about 35 per cent, which in his opinion is "insufficient for practical purposes."

Hirst concludes that "there would be much greater economy in the administration of vaccines of this type if they were given in the face of an outbreak, after its identification, rather than if the vaccine was administered in advance of each epidemic season, since the exact seasonal onset and yearly periodicity of influenza epidemics is too capricious to permit accurate prediction." Other investigators³ have shown that influenza immunity may be expected within eight days following administration of a nonviable vaccine.

Current Comment

MEDICAL EDUCATION AND INDUSTRIAL HEALTH CONGRESSES CANCELED

In response to the urgent request of the U. S. War Committee on Conventions and in accordance with the plea of the director of War Mobilization and Reconversion, James F. Byrnes, the Annual Congress on Medical Education and Licensure, which had been scheduled to meet at the Palmer House in Chicago February 12 and 13, and the Annual Congress on Industrial Health, scheduled for the Drake Hotel February 13-15, have been canceled. The decision not to hold these important meetings was made only after careful consideration of all the factors involved. The schedules of these congresses had been planned to deal principally with problems connected directly with the war effort. In order that the material prepared may be made widely available, those who were to have appeared on the programs of these congresses will be asked to send their papers to the respective secretaries of the Council on Medical Education and Hospitals and the Council on Industrial Health. These papers will then be considered for publication in full or in abstract in *THE JOURNAL* and will be included in full in special reprints which will be available to interested persons.

A PRACTICAL METHOD FOR DETERMINATION OF BLOOD VOLUME WITH THE DYE T-1824

A number of methods have been devised for determination of blood volume; the dye method of Keith and Rowntree has probably been of the greatest clinical value. The method, however, with the modifications introduced in order to secure greater accuracy, has become elaborate and time consuming and requires expensive equipment. Gregersen¹ has described a new dye method which was recently developed for the armed forces. The new technic is the result of several years' work on various aspects of the dye method and of two years' experience with blood volume measurements in various types of experimental shock in animals and in the study of shock in man. According to Gregersen the assumptions on which the determinations of blood volume are based have been extensively tested under abnormal as well as normal circulatory conditions and have been confirmed by factual data. From this evidence it is possible to define the limits of the error introduced by simplifying the determination on man and to show that this error is negligible in comparison with the reduction in blood volume observed in shock caused by trauma or hemorrhage. Briefly the method includes the following steps: 1. The plasma concentration of the dye T-1824 is measured with the portable Decade Photometer designed by Nickerson. 2. The total plasma volume is obtained from the dye concentration in a single blood sample drawn ten minutes after the dye injection. 3. The critical and troublesome procedure of measuring out an exact amount of dye at the time of making the determination is eliminated by using ampules containing a standard amount of dye solution of known concentration. This also eliminates all calculations from the determination of total plasma volume. By reference to a chart the plasma volume is obtained directly from the Decade Photometer reading. The total blood volume is then calculated from the plasma volume and the hematocrit. 4. The hematocrit may be determined with the copper sulfate-specific gravity method instead of with a high speed centrifuge. With the addition of the latter technic all the equipment is readily portable. This method makes it possible to determine the plasma volume and the total blood volume rapidly and with sufficient accuracy for practical purposes. Since the reduction in blood volume precedes the appearance of the symptoms of shock, it constitutes a valuable prodromal sign. Early determination of blood volume may therefore be useful as a means of predicting whether or not shock is impending. With this information available, shock can be combated before it develops. Intravenous therapy aims to achieve restoration of the normal volume as well as the normal composition of the blood.

1. Gregersen, Magnus L.: *A Practical Method for the Determination of Blood Volume with the Dye T-1824*, J. Lab. & Clin. Med. 29: 1265 (Dec.) 1944.

The data furnished by the hematocrit and plasma protein measurements may be misleading. Gregersen points out that the danger lies not only in failure to maintain an adequate blood volume but also in the excessive use of plasma and of other blood substitutes, thereby running the risk of inducing heart failure or pulmonary edema. In these cases a determination of the blood volume provides a reliable guide to therapy.

EXPERIMENTAL HYPERCHROMIC ANEMIA

Currently no entirely satisfactory experimental procedure is available for the assay of the anti-pernicious anemia factor. Much interest, therefore, attaches to a recent report by Davis¹ on the production of a hyperchromic anemia in dogs. Choline chloride in doses of 10 mg. per kilogram of body weight was administered once daily by mouth for twenty-five days and then the same amount was given three times a day. A reduction of 30 to 43 per cent occurred in the number of erythrocytes, with a concomitant increase in the color index and also in the relative volume index. The anemia would therefore appear to have hematologic aspects of pernicious anemia. Furthermore, intramuscular administration of purified liver extract and of dried stomach brought about a remission of the condition accompanied by mild reticulocytosis, despite continued choline feeding. The suggestion is made that retardation in erythropoiesis is brought about by the choline through vasodilatation in the marrow, thus producing the observed anemia. Whether or not these promising observations lead to an experimental method for estimating quantitatively the anti-pernicious anemia factor depends on further coordinated laboratory and clinical investigation.

SPECIAL SCHOOLS FOR CHILDREN WITH HEART DISEASE

The Jesse Spalding School is one of four elementary schools in Chicago designed to furnish normal school and environmental education for physically handicapped children. Children with cardiac disorders have been admitted to these schools as a group through the influence of the Chicago Heart Association since 1924. Recently Kohn and McEldowney² surveyed a group of children who attended the Spalding school. The survey covered approximately a ten year period. Of the 130 examined and interviewed, 104 had either improved or remained in the same cardiac classification since leaving the school. The youngest was 17 years of age and the oldest 33 at the time of the recheck physical examination. There were 65 males and 65 females. Thirty-two of the women were married; 14 had borne 1 child, 3 had 2 children, 1 had 3 children, 2 had had four pregnancies and 2 were pregnant at the

time rechecked. None of them reported that the heart condition had adversely influenced the pregnancy or labor to any great extent. Almost all in the group were working, and their jobs covered a wide range of occupations, including a commercial artist, an office worker, a butcher, a plumber's helper, a coal man, a truck driver, a waitress and a soldier. The investigators concluded that a special school for cardiac children can carry on where the convalescent home leaves off and enables the long continuance of the kind of medical supervision which a child with rheumatic heart disease requires. Such a school also makes for a more normal life for cardiac children of school age with limited capacity for activity and, through the contacts made with parents as well as children, facilitates their education in the practical aspects of the type of living suitable for them as children and adults. This experience confirms the advantages of the special school for children with heart disease and suggests the extension of this type of endeavor to other communities where it may be practicable.

PALMAR SWEATING

Anatomically there are more sweat glands per square area in the palm than anywhere else in the body. The amount of perspiration on the palm, according to Kuno,¹ is from five to ten times as great as that of the general body surface. Palmar sweating differs from that of the general body surface because under ordinary conditions it is not influenced by outside temperatures. Mental stimuli may evoke palmar sweating, and the palm is one of the few places where emotional sweating occurs. Silverman and Powell² developed a colorimetric test for determining the presence and the amount of palmar sweating. Ordinary mimeograph paper is soaked for three minutes in a 5 per cent solution of tannic acid, dried and cut into the desired dimensions. The part to be tested is thoroughly dried, after which 25 per cent solution of tincture of ferric chloride is evenly applied to the area with a cotton applicator. The area is then dried thoroughly and contact is made immediately thereafter between the chemically treated paper and the part to be tested. Contact is maintained for three minutes. The tannic acid reacts with iron to form a stain on the paper ranging between gray blue and blue black. The size and intensity of the resulting pattern are directly proportional to the amount of sweat secreted. The authors studied the palmar sweating response in 1,100 patients in an army general hospital. A high percentage of these patients showed manifestation of a disturbed autonomic nervous system, one of the striking features of which was palmar sweating. The authors conclude that excessive palmar sweating is a cholinergic phenomenon related particularly to emotional activities. Viewed in this light the determination of the intensity and the amount of palmar sweating acquires a special clinical significance.

MEDICINE AND THE WAR

ARMY

DRIVE TO ENLIST WACS FOR HOSPITALS

General of the Army George C. Marshall, chief of staff, U. S. Army, recently announced a new and vigorous recruiting drive to enlist Wacs for the newly created Women's Army Corps Medical Units for service at the Army's sixty general hospitals in this country. Women qualified for training as medical and surgical technicians, clerical workers and other skilled women are urgently needed to fill these hospital units to aid in the care and rehabilitation of returned soldiers and release able bodied men from technical and administrative duties. More than 8,000 additional Wacs are required for this purpose.

The plan is to assign a company of 100 women to each of the 1,000 bed hospitals and an additional company of the same size for each additional 1,000 beds in the larger hospitals. These companies will be made up of medical and surgical technicians primarily but will include some women of clerical skills and technicians in other fields, such as x-ray, laboratory and dental. Under an accelerated training program prepared by the Surgeon General's Office, qualified women enlisted as medical and surgical technicians will be assigned to a hospital unit as students after six weeks of basic military training and six weeks at an enlisted technicians' school. They will receive one month of applicatory training after assignment to the hospital. On satisfactory completion of this training they will qualify as technicians with appropriate army ratings and will continue on duty at the place of their final training.

One all Wac enlisted technicians' school has been set up at Wake General Hospital, Camp Atterbury, Indiana, and three others, formerly used to train men, have been opened at Beaumont General Hospital, El Paso, Texas, Fitzsimons General Hospital, Denver, and Brooke General Hospital, Fort Sam Houston, Texas.

LIEUTENANT COLONEL DAN B. SEARCY MISSING IN ACTION

Lieut. Col. Dan B. Searcy, formerly of Washington, D. C., has been missing in action since January 1943. He enlisted in the Army Medical Corps in 1938 and was sent to the Philippine area in 1941. He had a miraculous escape from Mindanao after the fall of Bataan and afterward was stationed in Australia and New Guinea. On Jan. 18, 1942 Colonel Searcy left on an inspection trip by plane and failed to return to his base. The weather was bad and the flight was over uncivilized enemy territory, which prevented any possibility of search or investigation of the loss of the ship. Colonel Searcy has been awarded the Legion of Merit Medal for exceptionally meritorious conduct in the Philippines between Dec. 1, 1941 and April 20, 1942. According to the commendation "No hospital facilities whatever existed on Mindanao, and bombing and strafing of the air base installations started right after Pearl Harbor. During this period Colonel Searcy set up and maintained full base medical and hospital facilities in spite of enemy activity. He maintained an ambulance at the airdrome, and on numerous occasions when bombing and strafing killed and injured personnel on the airfield he personally rendered first aid and directed removal of the injured." Dr. Searcy graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1934.

BRIGADIER GENERAL SIMMONS APPOINTED LECTURER

Brig. Gen. James S. Simmons, chief, Preventive Medicine Service, Office of the Surgeon General, U. S. Army, was recently appointed by the regents of the University of Michigan as nonresident lecturer in the School of Public Health for the university year 1944-1945.

46TH GENERAL HOSPITAL CITED

The 46th General Hospital, staffed by Oregon physicians and nurses and known as the University of Oregon Medical School Hospital, was recently awarded the meritorious service unit plaque. The citation mentions the efficient and rapid manner in which the hospital organized for treatment of casualties and for its high quality of professional work. The unit was last reported to have been on a beach head on the Gulf of San Rafael in southern France, and it is believed to be the first hospital unit to receive such honors. Col. J. Guy Strohm, Portland, is commanding officer of the 46th General Hospital and was recently awarded the Bronze Star.

AVIATION MEDICAL EXAMINERS

Graduation exercises for a class of fifty-nine medical officers who successfully completed the Aviation Medical Examiners' Course were held January 5 in Stafford Hall at the Army Air Forces School of Aviation Medicine, Randolph Field, Texas. The graduation address was made by Brig. Gen. Aubrey Hornsby, chief of staff, AAF Central Flying Training Command, Randolph Field, Texas. Presentation of the diplomas was made by Brig. Gen. Eugen G. Reinartz, commandant of the school.

FIVE MORE HOSPITAL SHIPS

The War Department stated that five more troop ships will be converted into United States Army hospital ships in order to insure speedier return of America's combat wounded. This addition will bring the number to twenty-nine such vessels operated by the Transportation Corps, Army Service Forces, and will have a total capacity of more than 18,000 sick and wounded. Conversion of the new ships is expected to be completed so that they will be ready for use in June or July.

24TH ANNUAL REUNION OF BASE HOSPITAL NO. 19

The 24th annual reunion and dinner of U. S. Base Hospital No. 19 Association was held January 27 in the Empire Room of the Powers Hotel, New York. The personnel of this unit was organized, equipped and trained under the command of Col. John M. Swan and was made up of doctors, nurses and men from New York. It functioned overseas as a 4,000 bed hospital in Vichy, France.

LIEUTENANT COLONEL LEON H. WARREN APPOINTED TO NATIONAL RESEARCH COUNCIL

Lieut. Col. Leon H. Warren, formerly of Philadelphia, has been appointed a member of the National Research Council, representing the War Department in the Division of Medical Sciences. Colonel Warren is now assistant director, technical division, Office of the Surgeon General, and liaison officer to the National Inventors Council.

NEW CONVALESCENT HOSPITAL ESTABLISHED

The War Department recently announced the establishment of a new convalescent hospital at Camp Upton, New York. The hospital will be under the command of Col. Edward A. Coates, M. C.

PRISONER OF WAR GENERAL HOSPITAL

The War Department recently announced that the hospital at Camp Forrest, Tennessee, is designated Prisoner of War General Hospital No. 2.

ARMY AWARDS AND COMMENDATIONS

Captain Morton M. Spielman

The Bronze Star Medal was recently awarded to Capt. Morton M. Spielman, formerly of New York. The citation accompanying the award read "for heroic achievement in connection with military operations against an enemy of the United States in —, France, on Nov. 12, 1944. Shortly before dark a group of vehicles, while crossing a treadway bridge, received a concentration of enemy artillery fire. Five men in the advance vehicle were seriously wounded and were in urgent need of medical aid. When Captain Spielman reached the bridge he found that the artillery fire was still falling in the area and that the vehicles had continued onward in order to get out of the area. Owing to the intense fire he was forced to leave his vehicle and proceed on foot. Accompanied by his driver he walked through one burning town and proceeded to the next, where he quickly set up his emergency aid station and rendered medical aid to the unit. Two of the men required immediate surgical attention and blood plasma. He performed the necessary surgical treatments under the most adverse conditions, and as a result of his efforts the men survived." Dr. Spielman graduated from the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, in 1937 and entered the service Aug. 1, 1942.

Major General Morrison C. Stayer

The Distinguished Service Medal was recently awarded to Major Gen. Morrison C. Stayer, formerly of Easton, Pa. The citation read "While serving as chief health officer, the Panama Canal, from September 1939 to February 1944, in the face of unprecedented difficulties, his untiring efforts and wise judgment resulted in the maintenance of exceptionally high standards in the Canal Zone and in the cities of Panama and Colon, and in the provision of adequate hospital facilities and personnel. His genius for organization proved invaluable to the government. The manner in which he met all responsibilities placed on him made possible greatly improved health conditions locally and played a large part in the outstanding results achieved in the field of health and sanitation. By his qualities as an officer, a

very difficult situation dealing with standards of sanitation was handled in a superior manner. He rendered invaluable service in the recruiting of laborers from Central and South America for vital defense programs in the Caribbean area." Dr. Stayer graduated from Jefferson Medical College of Philadelphia in 1906 and was commissioned in the regular Army in 1908.

Lieutenant Colonel R. B. Sigafos

At special ceremonies at the Office of the Surgeon General, the Legion of Merit was awarded to Lieut. Col. R. B. Sigafos, deputy director of the training division. He was cited for the outstanding work he did in training and equipping the medical units for the entire new Chinese First Army. Almost insurmountable obstacles of supply and personnel problems, particularly language differences, had to be overcome in the performance of this job. Major Gen. Norman T. Kirk, the Surgeon General, made the presentation. Dr. Sigafos, formerly of Tacoma, Wash., graduated from the University of Nebraska College of Medicine, Omaha, in 1937 and entered the service in August 1939.

Lieutenant Colonel Noah Barysh

The Silver Star was recently awarded to Lieut. Col. Noah Barysh, formerly of New York City, "for gallantry in action in the vicinity of Kej el Guelbi, Tunisia. Although subject to intense artillery fire, Lieutenant Colonel Barysh established a successful chain of medical evacuation units designed to secure maximum efficiency in the care of the wounded. Lieutenant Colonel Barysh repeatedly exposed himself to enemy fire on numerous inspections of aid centers under his command." Dr. Barysh graduated from Rush Medical College, Chicago, in 1933 and entered the service Dec. 21, 1940.

Captain John F. Larsell

The Purple Heart was recently awarded to Capt. John F. Larsell, formerly of Portland, Ore. He was wounded on Sept. 30, 1944 in action in the Nancy-Metz area of France. Dr. Larsell graduated from the University of Oregon Medical School in 1943 and entered the service Dec. 26, 1943.

NAVY

NAVAL AIR PHYSICAL DIRECTOR

Comdr. William R. Kane, U.S.N., was recently appointed head of the Naval Aviation Physical and Military Training Program, succeeding Comdr. Frank H. Wickhorst, U.S.N.R., who has reported for duty at sea. Commander Kane has assumed new duties after many months of combat in the Pacific, where he headed the famous "Grim Reapers" Squadron, which won the Navy Cross for leading a flight group against the Japanese fleet, received two Distinguished Flying Crosses for action at Truk and Palau and a Presidential Unit Citation as a flier on the U. S. S. *Enterprise*.

HOSPITAL CORPS SCHOOL FOR WAVES

The Hospital Corps School for members of the Women's Reserve at the National Naval Medical Center, Bethesda, Md., recently celebrated its first anniversary. Since its inception the school has graduated 5,825 women from a four weeks course which includes classes in first aid, anatomy and physiology, properties of drugs, hygiene and sanitation, nursing, dietetics, weights and measures, medication and sterilization. Under this system the school has been graduating 480 Wave hospital corpsmen each month. In class, junior students are instructed by Wave pharmacist's mates, first class, while senior students receive graduate training from the staff of Navy nurses assigned to the school under the direction of Lieut. Clara Alice Stolp, Nurse Corps, U.S.N.R. The students are sent to the school on completion of recruit training at Hunter College, Bronx, New York, and are under the direct supervision of Comdr. Martin V. Brown, Medical Corps, U.S.N., executive officer in charge of the Hospital Corps School. Graduates of the school are stationed at naval hospitals and in the dispensaries of naval

air stations, training centers and all naval establishments within the continental United States where their services are needed. With the passage of the overseas bill for Waves, a number of these hospital corpsmen have recently been assigned posts in Hawaii.

NAVY AWARDS AND COMMENDATIONS

Lieutenant Stephen L. Derkach

Lieut. Stephen L. Derkach, formerly of Glen Rogers, W. Va., was the recent recipient of the Bronze Star. The citation read "for meritorious performance of duty as a company medical officer of the Second Beach Battalion during the assault on France, June 6, 1944. Lieutenant Derkach, under heavy gunfire, repeatedly exposed himself to administer to the wounded and, without regard for his personal safety, supervised the evacuation of wounded from his section of the beach. His courage and devotion to duty were an inspiration to all officers and men having contact with him. The skill and professional ability displayed by Lieutenant Derkach under most trying conditions were in keeping with the best traditions of the United States naval service." Dr. Derkach graduated from Hahnemann Medical College and Hospital of Philadelphia in 1940 and entered the service Dec. 21, 1942.

Lieutenant Ernest V. Reynolds

The Bronze Star was recently awarded to Lieut. Ernest V. Reynolds, formerly of Barre, Vt., "for meritorious performance of duty as senior medical officer of the Second Beach Battalion, United States Navy, during the assault on the coast of France, June 6, 1944 and subsequently. Lieutenant Reynolds organized

the medical section of the beach battalion and exerted the leadership which enabled medical attention to be brought to casualties on the assault beach shortly after H hour, initiated casualties evacuation on D day and continued it thereafter despite the extremely unfavorable type of beach, shortage of supplies and fire and bombing from enemy airplanes and surface batteries. The bravery and professional ability displayed by Lieutenant Reynolds during this period were in keeping with the best traditions of the United States naval service." Dr Reynolds graduated from Cornell University Medical College, New York, in 1934 and entered the service Nov 16, 1942.

MISCELLANEOUS

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

Induction Center Grand Central Palace, New York Head Injuries, Dr Eli Jefferson Browder, February 9 (to be repeated on February 16).

Gardner General Hospital, Chicago Brain and Spinal Cord Injuries, Dr Eric Oldberg and Dr Adrien H P E Verbrugghen, January 31, Less Familiar Vascular Syndromes, Dr LeRoy H Sloan, February 7 Present Status of Medical Planning, Dr Morris Fishbein, February 21

Station Hospital, Truax Field, Wisconsin Allergic States, Dr Theodore L Squier, January 31, Effects of Cold and Dampness, Col Irving S Wright, February 14, Heart Disease, Dr Chester M Kuntz, February 28

U S Naval Hospital, Great Lakes, Ill Differential Diagnosis of Some Common Skin Diseases, Dr Francis Seneary, February 6

Birmingham General Hospital, Van Nuys, Calif Some Aspects of Peptic Ulcer, Dr William Boeck, February 14

Regional Hospital, Camp Haan, California Repair of the Facial Nerve, Dr Pierre Viole, February 6

Station Hospital, Camp Cooke, California (afternoon session) and Hoff General Hospital, Santa Barbara, Calif (evening session) Pathogenesis of Rheumatic Fever, Lieut Comdr Robert W. Huntington Jr, February 7, Clinical Aspects and Treatment of Rheumatic Fever, Lieut Comdr George C Griffith, February 7

Torney General Hospital, Palm Springs, Calif Peripheral Nerve Surgery, Dr Rupert Ranev, February 6, Intestinal Obstruction Due to Regional Enteritis, Lieut Col W A Sheehan and Major Ralph Pomeranz, February 6

U S Naval Hospital, Corona, Calif Anesthesia, Major C H Wainock and Lieut J E Skewis, February 8

AAF Regional Hospital, Santa Ana Air Base, Santa Ana, Calif Thoracic Surgery, Lieut Comdr J E Dailey and Dr John Jones, February 6

Station Hospital, Fort Sheridan, Ill Plexus and Peripheral Nerve Injuries, Dr Paul C Bucy, January 31

Vaughan General Hospital, Hines, Ill Endocrinology, Dr Willard O Thompson, January 31

Mayo General Hospital, Galesburg, Ill Burns and Plastic Surgery, Col William B Parsons and Dr Christopher Dr., January 31

Station Hospital, Camp Ellis Lewistown, Ill Psychosomatic Medicine, Dr Sidney A Portis, January 31

Regional Hospital, Chanute Field, Rantoul, Ill Arterial Vascular Disease—Traumatic Lesions, Dr Theodore R Van Dellen and Major Harris Shumacker, January 31

Wakeman General Hospital, Camp Atterbury, Indiana High Blood Pressure, Dr Kenneth G Kohlstadt and Dr Robert L Glass, January 31

Billings General Hospital Fort Benjamin Harrison, Indiana Diseases of the Kidneys—Urogenital Tract, Dr James O Rutchey and Dr Henry O Mertz, January 31

A A F Regional Hospital, Santa Ana, Calif Thoracic Surgery, Dr John Jones and Lieut Comdr J. E Dailey, February 6

U S Naval Hospital, Oceanside, Calif Allergies of Southern California, Dr Robert W Lamson, February 8

NEW ADVISORY AND CONSULTANT APPOINTMENT FOR REAR ADMIRAL SMITH

Rear Admiral Harold W Smith (MC), USN (Ret), Head of the Research Division of the Bureau of Medicine and Surgery, has been appointed a member of the Advisory Scientific Board of the Gorgas Memorial.

Admiral Smith also has been appointed a member of the Permanent Board of Honorary Consultants of the Army Medical Library.

U S Naval Air Station, North Island, San Diego, Calif Blood Plasma and Blood Substitutes, Lieut Col R M Jones February 9

Mary Lanning Hospital, Hastings, Nebr New Drugs in 1943 and 1944, Dr Lynn T Hall, Nontuberculous Diseases of the Chest, Dr Francis L Simonds, Routine Use of Protein Digest Intravenously Following Major Surgical Procedures, Dr Herbert H Davis, February 7

Air Base Hospital, Patterson Field, Dayton, Ohio Diagnosis and Medical Management of Cholecystitis, Dr C J De Lor, Surgical Treatment of Acute Cholecystitis, Dr John W Means, February 21

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, January 20, page 164)

CONNECTICUT

Waterbury Hospital Waterbury Capacity, 372, admissions 840⁷
Miss Aida E Creer, RN, Superintendent (5 interns, July 1)

ILLINOIS

Loretto Hospital, Chicago Capacity 159 admissions 4221 Sister M Stephanie, RN, Superintendent (interns)
Swedish Covenant Hospital, Chicago Capacity, 256, admissions 6365
Mr Arthur A R Nelson, Superintendent (interns, July 1)

LOUISIANA

North Louisiana Sanatorium Shreveport Capacity, 121, admissions 3,856 Dr A A Herald President (intern)

Sister M Bernadette, RN, Superintendent (intern, July 1, September 1)
State of Wisconsin General Hospital, Madison Capacity 772, admissions 12682 Dr H M Coon, Superintendent (resident—medicine)
Evangelical Deaconess Hospital, Milwaukee Capacity, 170, admissions 5465 J P Meyer, D.D., Superintendent (intern October)
Mount Sinai Hospital Milwaukee Capacity, 198 admissions 9551
Dr M Rosenzweig, Superintendent (intern, July 1)

ORGANIZATION SECTION

ANNUAL CONFERENCE OF SECRETARIES AND EDITORS OF CONSTITUENT STATE MEDICAL ASSO- CIATIONS

SATURDAY MORNING SESSION, NOVEMBER 18

DR. D. L. CANNON, Montgomery, Ala., Presiding

(Continued from page 169)

Medical Attitudes, Opportunities and Responsibilities in a National Fitness Program

DR. J. W. WILCE, Columbus, Ohio: We have in America today a challenging movement to improve the health and fitness of our people. This new program is full of vital potentialities, and progress has already been made. The medical profession is deeply concerned. In this war, as in World War I, the high percentage of rejections for service startled America. Following World War I new laws were passed in thirty-six states which required physical education and health education in the public schools. The requirements ranged from forty minutes to three hundred minutes a week. We required one hundred minutes a week in Ohio, and even this law was recently repealed. In spite of these new exercise, recreation and health education laws and various national health conferences, improved public health administration, vastly increased sports facilities and programs in the interim, the percentage of draft rejections in this war is as great as in the first, if not greater. Even relatively scientific analysis of reasons for this seeming condition cannot be made except by those who have the detailed findings and adequate case histories of rejectees and medically discharged veterans. I hope that an analysis of records may be made by some proper agency at a proper time, in the interest of future human improvement.

The appointment of the Committee on Physical Fitness in the Administrative Office of the Federal Security Agency was made in April 1943. John B. Kelly, Olympic single sculls champion, is chairman of this committee by presidential appointment. A joint committee on physical fitness equally representative of the Council on Physical Fitness and the American Medical Association was established. The platform adopted by the Joint Committee on Physical Fitness has as its objective to 1) help each American to learn physical fitness needs, (2) protect against preventable defects, (3) attend to correctable defects, (4) know how to live healthfully, (5) act to require physical fitness, (6) set American standards of physical fitness at a high level and (7) provide adequate means for physical development. At the beginning of his military training the merely healthy boy is dead tired in the evening and falls asleep as soon as he finds a chance. After some months, however, he does the same and far more strenuous work with hardly any effort and takes leave for the evening. All the men gain an increase of strength and reserve strength, which is a physiologic reality and can be expressed in work hours. This conditioning to dynamic strength has been greatly neglected in peacetime; hence a large percentage of our selectees, even those who were healthy from the medical point of view, that is, had no specific defects or illnesses, were conspicuously weak and needed a long period of training and conditioning. It should be remembered, however, that the achievement and maintenance of basic clinical health is a prerequisite for the achievement of physical fitness. "The task of medicine will center around the recognition, prevention and correction of defects, deficiencies, disabilities, disorders and diseases." The fitness movement this time started out in approximately the same way as that of 1919, except that it was aimed nationally.

The joint committee includes the chairman Colonel Rowntree, medical head of Selective Service. There are seven physicians:

both presidents of the American Medical Association, Dr. Fishbein, Dr. Sensenich, Dr. Buie, Dr. Stroud and General Lull, also Dr. Wells and the president of the American Dental Association. On the other side of the fence we have the group that is theoretically directly concerned with physical fitness: the chief of the United States Office of Education, or his representative, Dr. Lloyd, and Dr. William P. Jacobs, president of Presbyterian College, Clinton, S. C. Incidentally, this fine type man is now privately publishing a very personable, attractive new magazine in the interest of the fitness movement. The magazine is called *Aim*. Also Dr. Hiram A. Jones, Ph.D. director of physical fitness for New York State; Mr. A. H. Pritzlaff, president of the American Association for Health, Physical Education and Recreation; Mr. Arch Ward of the Chicago *Tribune*, who has promoted the annual all star football game, and Watson B. Miller of the Federal Security Agency in Washington or his representative. Dr. Frank S. Lloyd, a Ph.D., has served as executive secretary. The assistant to the chairman is Dr. Franz Schuck. This joint committee has held monthly meetings since June. It set up a series of programing committees with co-chairmen, one a layman and one a physician. The committees are on institutional planning, management, labor, promotion, schools and colleges, associated industry, state and local, and medical affiliates.

As many of the members of these committees as could be brought together were gathered in a tremendously significant meeting and submitted tentative programs in Washington, July 28 and 29, 1944. Over a hundred people in these various fields attended this meeting. Since that time the joint committee has given most of its attention to the consideration of suggested programs. The practical picture at the moment is that schools and colleges submitted a valuable proposed plan, outlining much that is already being done in school health and suggesting various advances of educational and medical nature for future development. The Associated Industry, of which committee I have served as medical co-chairman, along with Mr. L. B. Icely, president of Wilson Sporting Goods Company, as chairman, has led the field in a recommended practical program. The government at the present writing has said in effect that it will not subsidize the movement further. The Federal Security Agency paid the traveling expenses of the more than 100 consultants to the big July Washington meeting. The American Medical Association has paid the expenses of its own representatives. I might say that the Ohio State Medical Society entered into that process also. The Associated Industry offers to raise money and to set up a corporation, not for profit, an executive secretary and a board of ten to conduct and promote the future activities.

What has all of this to do with medicine? The Medical Affiliates Committee, which includes state and local medical organizations, has never had an opportunity to meet in its completeness and strength. Dr. West and Dr. Van Etten have been the medical chairmen of this group. In a sense this meeting is the first in which the program is being presented to enough medical representatives on the state level to make it of significance. Practical suggestions to state associations as to the nature and degree of their cooperation in the joint movement have been delayed for many reasons. Medicine has been notoriously conservative in its approach to this movement and understandingly so. The present situation poses a challenge to the medical profession to get into this movement on high ground, but also bluntly stated and possibly off the record, on the same basis of enlightened self interest that has prompted the Committee of the Associated Industries.

The experience of the preflight naval physical training schools is significant. They started out with five hours a day physical training. They were going to make supernumeraries for aviation. Most of them are now having three hours a day physical training.

ing and sport and, the significant thing, including one hour of the Jacobson relaxation system. In other words, we did not know how far exercise could go to improve the physical fitness of the individual without defeating its own purpose. Two classes at one preflight school scored less in the final pack function test than they did on their entrance to the program.

The stamp of approval of the American Medical Association is an asset of untold worth. I cannot tell this group that. The medical profession should guard it jealously in this movement and in my opinion should withhold it until national, state and local organization is satisfactory to medicine. Proper state and local organization is prerequisite to the success of this movement, because that is where the results are going to be obtained and that is where the decisions are going to be made and the work is going to be done.

The general principles of the splendid statement published by the Council on Industrial Health in *THE JOURNAL*, Nov. 11, 1944, on general medical coverage for industrial employees are directly related to this particular discussion. In providing for this health negotiation and arrangement with industry is included the statement that plans of this nature should include provisions for health maintenance programs, that the physician should be responsible directly to top management and that activities relating to health should be centered in and directed through the medical department. Because of the essential medical nature of such plans, their policies should be directed and their medical phases should be controlled by the medical departments of industry. Much the same principles are appropriate to total community fitness programs, which of necessity include industry as the most immediately important field in the winning of the war from the home standpoint. I believe that Dr. West hopes that this meeting may serve as a start toward a clearance of some ideas on local procedure. The medical plans under which these tremendously increased medical and surgical services are effected will vary, of course. The present organization in some states is beneath the dignity of the medical profession and cannot succeed fully unless it is changed. I have been serving as a representative of the Ohio Medical Society, as a member of the State Advisory Committee, which first was called appropriately "The State Advisory Committee on Health, Recreation and Physical Education." With the same organization it has lately been called "State Advisory Committee on Recreation and Physical Fitness." The organization of the Joint Committee on Physical Fitness is a great victory for medicine, if we can make the principles stick on the state and local level. Our own state advisory committee adopted the principle that this joint committee has adopted. It called in industry last summer and got money from the Kellogg Foundation. The tuberculosis association of the state wangled that out of the Kellogg Foundation in good shape, and a physical educator was sent into the state as the guide of a school and community health program, subsidized by the Kellogg Foundation, the theory of the present situation in the joint committee. Medicine in a sense has to compete with education in the guidance of community health. This physical educator, a young woman, called in thirty-six teachers from high schools in the state. At a two week seminar she placed before them a great many authorities in many public health fields, and then she sent them home to organize senior classes in public health and community and school health programs with the general implication that the school superintendent was to promote and organize community health. I asked the girl about the make up of the committees organized by the superintendents to promote school health and out of the school to expand into a sort of adult education and these are the advisory committees that they set up. In the very small town of Mason they set up as the committee the PTA, American Legion, Eastern Star and Rebeccas, two elementary teachers, two high school teachers, the Red Cross and one local M.D. In a large city, Toledo, the Tuberculosis Association, the Chamber of Commerce, Health and Physical Education, Family Life Association, Social Hygiene Association, one parent of PTA, Toledo Blade representative and a school nurse. There is no mention of a physician among that community health promotion group. There may be one, but she did not mention him. Then in another small community which poses as the grass roots picture, here is the community

health committee set up in this particular small town through the superintendent of schools: the mayor, the president of the board of education, the superintendent, a minister, Kiwanis, a dentist, a chiropractor who is half time school physician, a science teacher, a Negro mother active in church, a publicity man and a mother with four children in school. Well, that is the slant local organization is taking in the absence of constructive health leadership from the standpoint of medicine. To me it poses the question as to whether a little more leadership should not be given through regular medical channels on the state and local level.

The basic responsibility of medicine is to participate to the limit of its vast influence through its every channel and medium in the fundamentally sound aspect of the program on all levels. The majority of interested people look for, expect and rely on such participation. Medicine should determine scientifically as far as possible the proper standards of medical and physical fitness and furnish such information to agencies and organizations which can and will use it constructively and conscientiously in the promotion of the movement. Medicine should attempt realistically to change the national, state and local organization to achieve a national, state and local organization of the type deemed best from the medical standpoint for the continued achievement of medical and physical fitness ends. Medicine should face the facts and attempt to educate those of our own membership who need it to the facts, appreciation of values and attitudes inherently necessary to the success of the movement. Medicine should consider seriously and promote the subsidization from medical funds of medical fitness offices, libraries and personnel for medical coordination, education and sound ethical promotional leadership of the profession and the public on national, state and possibly on local levels, as has been done in a limited way by organized medicine with health education. Another responsibility of medicine, of course, is to encourage research in the medical fitness and overlapping physical fitness fields and to exercise alertness and courage in the medical guidance and control of the inevitable attempts at overpromotion of the movement in some special interest.

DISCUSSION

DR. MORRIS FISHBEIN, Chicago: The hearings held before the Pepper committee having to do with the present state of health of American youth as determined by the examinations of the induction boards and Selective Service boards are likely to be a political football in the next few months in the Congress of the United States and in various public hearings. Those who would like to show that medicine has failed in its task of keeping the American people healthy and fit are emphasizing the tremendous number of rejections for various causes and cite these as a failure of the medical profession. Those who are on the defensive, which means the medical profession, are therefore compelled to point out that many of the rejections were for conditions which are neither preventable nor correctable. As Dr. Sensenich pointed out in his appearance before the Pepper committee and has emphasized in his article which appears in *Hygeia*, many of these defects, as, for example, illiteracy, are not in any way at the door of the medical profession. Some of these defects stem from conditions which are wholly economic.

If this state of health of American youth is to be related to the political situations, it is important for the medical profession to be able to say, as Dr. Roger Lee and Dr. Harvey Stone both said in their appearance before the Pepper committee, that the medical profession is assuming the leadership in raising the people of the United States to a high degree of health and physical fitness. We are in an exceedingly fine strategic position at the present time. The National Committee on Physical Fitness has now been changed to a Joint Committee on Physical Fitness, with representation from medicine. In all of the sessions that have thus far been held the medical point of view has prevailed. At present the governors of forty-two states have assured the organization that they propose to set up this movement on the state level. The governors were asked in the individual states to set up state committees, and an outline for a state committee has been sent to each of the governors who has responded favorably. It is proposed that in the setting up of the state committee to

guide this movement there be adequate representation of medicine from the state medical society and that the state medical society be asked to designate to the governor its representation on the state committee. There has also been set up the possibility of county or municipal organization for the same purpose, again the local medical society will be asked to exercise the medical guidance.

The promotion of the movement, as Dr Wilce pointed out, is going to require a large financial subsidy. An arrangement is now in process of being developed and will probably be consummated within the next two weeks whereby all of the industries concerned at all in the health field—the food industry, the athletics industry, the builders of gymnasium and physical equipment of all kinds, will establish the necessary funds. Any literature sent out in relation to this work will be controlled by a small committee which will be predominantly medical. The idea of a one year emphasis has been abandoned. The first to suggest that was Dr West, and I think wisely. As present the great numbers of physicians who are away from the country make it practically impossible to put into effect for the nation as a whole a complete physical fitness program such as is contemplated.

In analyzing the results of the induction boards, it becomes clear that we are not as a nation a degenerate and weak and flabby nation. A degenerate, weak and flabby nation could not have produced an army and navy of ten million men, such as we now have, and carry on the kind of battles that they are now carrying on. It is quite clear, however that frequently in the schools, in the high schools and colleges, we produce young men and women who are physically fit and that at the moment when the child leaves school, if it leaves grade school to go into industry, if it leaves high school to go into industry or if it leaves college or a university to go into industry or other work, degeneration from the physical point of view begins to set in. The School Health Association of the United States has emphasized that point. This means therefore, that we need a nationwide physical fitness movement which will reach the worker in industry regardless of the age level. This movement is now being set up with the idea of reaching that group particularly. Practically all of the great insurance companies of the country are coming into the picture. They realize that they have a special interest in prolonging life and in maintaining health on a high level. In order to carry this movement on there must be an integration of all of the groups concerned. While it is true that medicine must assume the leadership, I think it is equally obvious that medicine represents numerically the smallest group in the picture. When the associates were called into the meeting in Washington there were over one hundred national organizations which take it as a part of their work to carry on a physical fitness movement—the Y M C A, the Y W C A, the 4 H Clubs, the Association for Recreation in Industry and similar groups. They are all willing to accept medical leadership provided medicine assumes leadership.

From the point of view of medicine's self interest already mentioned by Dr Wilce, I doubt that there is anything more important to the advancement of medicine than the idea that, with the cooperation of state authorities and school authorities, physical examinations will be provided for boys and girls of all age levels. From a public relations point of view there is one of the most important opportunities for the medical profession in overcoming a good deal of public antipathy to some of the things that they think medicine stands for and getting the parents of the child closely in contact with the medical profession. The organization of medicine for this purpose, the committee has agreed shall be on the basis of the organization of the American Medical Association and its constituent and component societies. The county medical society and the state medical association will have to carry out many phases of this work. With the lack of available personnel in the medical profession at this time, it would be ideal if every association having a competent woman's auxiliary would enlist the interest of the woman's auxiliary in this project. Thus at least some one familiar with or sympathetic to medicine's programs could be present at every one of the various types of meetings that are going to be carried on in associated groups when this movement gets under way. In order to put this on

a sound medical basis the aid of the National Research Council Division of Medical Sciences, has been enlisted. There is to be a meeting of representatives of the medical profession, including particularly men expert in the field of cardiology and in the field of nerve and muscle physiology, including representative physical educators, to establish standards of physical fitness at various age levels. The public looks to the medical profession for advice and leadership in this field. Such advice and leadership cannot be given until the leaders of the medical profession—that means particularly in this instance the leaders on a state and county level—inform themselves fully about what is going on and thus are able to advise the lay groups who are going to look to you for leadership in this movement.

DR H. H. SHOULDERS, Nashville, Tenn. This movement offers an opportunity for medicine to place some emphasis where it belongs. The absence of physical fitness in young men is not entirely the fault of the medical profession. The parents of these youngsters, the educators and many other people are responsible for that rather than the medical profession. I think the public is too quick to emphasize the matter of a physical examination or even a tonsillectomy in the matter of establishing physical fitness. The matter of physical fitness is much broader than purely medical care. Parents are to blame. It is the heredity of the individual, the early training of the individual, the diet of the individual, the home—a thousand things contribute to physical fitness or the lack of it. I should regret it very much if we should ever permit this to become a purely medical movement. At the same time medicine must be in the picture in an advisory capacity and to a prominent extent. These promotions of athletics have never made athletics usable in the production of physical fitness of all the people. They have merely made it a propaganda outfit for the schools. That may be an exaggerated statement, but to a large extent it is true.

DR OLIN WEST, Chicago. I had this subject placed on the program with malice aforethought. The physical fitness movement is being organized on a national basis. I believe that the movement is a most important one and that it should have been started seventy-five years ago instead of at this late date. I have been made the chairman of a group, a programming group designated the Medical Affiliates. The question has arisen as to just how that group shall be composed in its final organization. May I interject the thought that we want to keep medicine in the forefront in this movement not only in a purely advisory capacity but in an authoritative advisory capacity. I do not believe that the movement can ever succeed unless it is largely directed by medicine, and I am sure that it can never succeed unless the medical profession on the state and local level will get wholeheartedly into the movement. My purpose in putting this subject on the program was that you, as secretaries and editors of the constituent state medical associations, might know about it and that I might have an opportunity along with the members of the Joint Committee on Physical Fitness, of which Dr Sensenich and Dr Fishbein who are present, are members, to appeal to you to give all possible aid on the part of state and county medical societies in the promotion and in the operation of this movement. It ought not to be organized on the basis of what exists in the large cities or in the large communities. It ought to be organized with a view to carrying this movement into the isolated communities and even into the strictly rural areas. It is my hope that our state medical associations and our county medical societies will develop programs and will wholeheartedly cooperate with those of us in the American Medical Association, including the Board of Trustees and our entire administrative personnel in putting this movement across.

DR LOU W. MORREY, Chicago. I came here to listen because I was sure that I would gather many thoughts from your deliberations that I could carry back to the American Dental Association that would help us in organizing our program on the state and local levels. The American Dental Association has been in a rather peculiar spot as far as this physical fitness program is concerned. From its inception at least from the inception of the joint committee, our immediate past president, Dr Raymond Wells, was a member of the joint committee but

the American Dental Association officially had not endorsed the program. However, I am happy to inform you that at our meeting last month the House of Delegates of the American Dental Association officially endorsed the program and agreed to cooperate to the fullest extent. We have had a little experience in this physical fitness program over the past two years, however. About two years ago we joined a cooperative movement with Mr. Studebaker of the United States Office of Education in the promotion of his High School Victory Corps Physical Fitness Program. Through the Council on General Health of the American Dental Association we asked our state dental societies and our component dental societies to cooperate with the state superintendent of instruction and the state board of health in the establishing of a Victory Corps Dental Program. It has been brought out here by both Dr. Wilce and Dr. Fishbein how difficult it is going to be to put this program over on the state and local levels. I can assure you from the experience that we have had over the past two years with this high school program that it is a difficult job to put it over. Forty-two states have established committees to cooperate with their state educational and health officials, but of those forty-two states only a few actually put over a statewide program. True in most of the states some of the local communities did a fairly good job in going into the high schools and in having the mouths of the high school students examined and then in following through to have the defects corrected, but the success of the program was very spotty. Dr. Fishbein pointed out, or at least I understood him to say, that in all probability this physical fitness program should be directed at the industry groups. I presume that it may work out that way but I do want to leave this thought with you. As far as the dental program is concerned, we would much prefer to direct our efforts at the school age child. You know just as well as I do that if we are going to control this dental decay situation and if we are going to develop better teeth the best way to do it is to concentrate our efforts on the younger age group to prevent the teeth from becoming decayed, so that we can prevent the installation of bridges and partial dentures. I am sure that I am speaking for the entire American Dental Association when I say that we would like to concentrate our efforts on the lower age group and that we would like to solicit your cooperation in setting up your state programs.

DR. JULIAN P. PRICE, Florence, S. C.: I have been wondering what the state secretaries and editors could actually do. One point that has been brought out which I think every one will recognize, particularly any of us who are pediatricians, as I am, is the apathy on the part of the average practitioner toward the care or the examination of any one who is not actually sick. The average physician does not worry about the child, or even the adult, who comes in without a fever or without a pain. Yet no program of this type can get across in the smaller communities, in the rural communities, unless our general practitioners become interested in the prevention of disease and in the maintenance of good health. The year before the war in my community they put on the type of examination which Dr. Fishbein mentioned at various levels for all the children. It was one plan about which the physicians should have been enthusiastic, and yet only one physician in the community took any interest whatever in it. It seems to me that one of our problems is to educate through the state journals and otherwise the physicians toward a new concept of what health is. We cannot do it suddenly, but we can do it gradually through our editorial columns and otherwise. The Rowntree report, as Dr. Fishbein brought out, is going to be a political football. A great many of the defects which threw these men out of the Army could have been remedied if these boys had gone to their family physicians for examinations. The family physicians did not want to examine them. We have to change that attitude on the part of the family physicians. We must make them realize that either we are going to take the leadership in keeping the nation fit or somebody else is going to do it. In the larger communities where there are school physicians who are employed, they can do the examinations; but in the smaller communities, in the rural communities, it is going to be the family physician who has to do it. I am not so old that I cannot remember the time when the average family

physician did not want to bother with giving shots to prevent diseases in children. I think the pediatricians have blazed the way. Whether the general physicians wanted to do it or not, they have had to do it in self defense or lose their patients and now it has become routine. My plea would be that every editor here of a state journal make it his resolve for the next year or two or three years to carry on a slow but gradual process of education through his state journal, aimed at the family physician and his responsibility in the whole picture.

DR. WEST: Dr. Price, don't you think it is possible that the institution and promotion of this movement, with the cooperation of the officials of the state and perhaps county medical societies, might offer the best opportunity for getting those ideas into the heads of these doctors that you are talking about?

DR. PRICE: I have always realized that doctors are stubborn individuals. They are not going to take advice from the outside. If it comes through the state association and not from somebody else, they will take it.

DR. R. L. SENSENICH, South Bend, Ind.: I want to point out that one feature of this work has not been specifically mentioned; that is, in connection with the improved methods of teaching health in the public schools. The limited amount of health information that is taught to the youngsters in many instances is so presented that it is the least interesting. It is given a place by the authorities rather hesitantly. In many instances we find that superintendents of schools are really pushing all health matters off to the side; if they have a program in which the individual children are given a certain number of squats and arm exercises and a little swimming at regular intervals, that seems to constitute their interest in health. In many states now steps are being taken to cover the whole field, which includes improved methods of teaching and improved methods of presentation as well as the requirement of these exercises that have been set up. Secondly, this is not purely a victory program. It is a matter of trying to instill into the youngster as well as the employee in industry the importance of health as an objective in itself, so that they will be willing to accept those things that are necessary for the maintenance of health in industry and so that the individual coming out of school will not begin this rapid deterioration at the end of his school period. We have been told, where inventories have been made, as Dr. Fishbein pointed out, that children coming out at the high school level can just take the routine Army induction examinations almost 1, 2, 3, except for those conditions which are largely congenital or where requirements are set up in the way of visual standards, and so on, that they cannot meet.

In the main their physical fitness is pretty good, but they begin to deteriorate from that point on because health in itself is not considered an objective. They are unwilling to accept the self disciplines necessary for the maintenance of health, and the same is true in nutrition. Much is said constantly about the medical profession taking the leadership. It depends on what you mean by leadership. Many times that means setting up a pattern or saying what shall be done. In this instance we have the backing of an influential group that will supply funds. We have the opportunity here of a favorable relationship with government and with education. Here then is an opportunity for the medical profession to exercise that leadership. In essence it means that every one of you down in your state and county societies must also be leaders. You must lead in your own communities.

DR. J. W. WILCE, Columbus, Ohio: Dr. Fishbein said that they are sending an outline of state organization to the states. In the last meeting of our state organization I outlined for the ladies and gentlemen the national organization as it is, and I said that in my opinion this was going to add great vitality to the movement. Imagine my delight and surprise to have the physical education chairman come back and say "We had a letter from the joint committee, from Colonel Rowntree, asking us to do these things, and I have written him saying that we are getting along very nicely." The point about the pediatricians was swell. If they would take more interest in scarlet fever and measles we would have fewer ruptured ear drums to take these 218 pound all American ends out of the Army.

(To be continued)

THE HILL-BURTON HOSPITAL CONSTRUCTION BILL

An Analysis Prepared by the Bureau of Legal Medicine
and Legislation, American Medical Association

During the course of the hearings conducted by the Pepper Subcommittee on Wartime Health and Education of the Senate Committee on Education and Labor, the Surgeon General of the United States Public Health Service on July 12, 1944 outlined a broad program for federal participation in the construction of hospitals and related facilities. Subsequently a draft of a bill was prepared and recommended for discussion by the Council on Government Relations of the American Hospital Association to the joint committee of the three national hospital associations: the American, the American Protestant and the Catholic Hospital Associations. The draft was discussed at a meeting of the joint committee held in Washington, Nov. 4, 1944. Representatives of the American Medical Association, by invitation, participated in the discussion.

A number of changes in the draft were suggested and some of these were embodied in a revision of the draft which was introduced in the Senate, Jan. 10, 1945, by Senator Hill of Alabama, for himself and Senator Burton of Ohio, as S. 191. The bill was referred to the Senate Committee on Education and Labor, of which Senator Murray of Montana is the new chairman. It is assumed that this bill will be considered by the recently announced standing subcommittee of nine of the Senate Committee on Education and Labor, which has been created to consider proposed legislation on health. Senator Claude Pepper, Florida, will head the new subcommittee. Other members are Senator James M. Tunnell, Delaware; Senator Elbert D. Thomas, Utah; Senator Robert M. LaFollette, Wisconsin; Senator Kenneth S. Wherry, Nebraska; Senator Lister Hill, Alabama; Senator James E. Murray, Montana; Senator Robert A. Taft, Ohio, and Senator George D. Aiken, Vermont.

PURPOSES OF S. 191

The declared purposes of the pending bill are twofold: (1) to assist the several states to inventory their existing hospitals, as that term is defined in the bill, to survey the need for new construction and to develop programs for construction of such public and other nonprofit hospitals as will, in conjunction with existing facilities, afford the necessary physical facilities for furnishing adequate hospital, clinic and similar services to all people; and (2) to construct public and other nonprofit hospitals in accordance with such programs.

DEFINITION OF TERM "HOSPITALS"

The term "hospital" is broadly defined to include "public health centers and general, tuberculosis, mental, chronic disease and other types of hospitals and related facilities, such as laboratories, outpatient departments, nurses' home and training facilities, and central service facilities operated in connection with hospitals." The definition, however, excludes any hospital furnishing primarily domiciliary care.

CREATION OF FEDERAL ADVISORY COUNCIL

To assist in administering the provisions of the bill on a federal level, a Federal Advisory Council is proposed. The Surgeon General of the Public Health Service will serve as chairman ex officio of the council, and the other eight members will be appointed by the administrator of the Federal Security Agency. The appointed members will be persons "who are outstanding in fields pertaining to hospital and health activities, and a majority of them shall be authorities in matters relating to the operation of hospitals." Their terms of office will be staggered. They will be compensated at a rate fixed by the administrator of the Federal Security Agency but not to exceed \$25 a day while serving on business of the Council and will be entitled to receive an allowance to cover expenses while serving away from their places of residence. The Council must meet at least once a year but may meet more frequently if the Surgeon General deems it necessary. On the request of three or more members, it is made mandatory that the Surgeon General call a meeting.

STATE ADVISORY COUNCILS

Applications that will be submitted to the Surgeon General for approval, proposing surveys of existing facilities and the development of programs for construction, must provide for the designation of state advisory councils to include representatives of "nongovernment organizations or groups, and of state agencies, concerned with the operation, construction or utilization of hospitals, to consult with the state agency in carrying out such purposes."

FEDERAL APPROPRIATIONS

For the fiscal year ending June 30, 1946, total appropriations of \$110,000,000 are proposed. Of this amount \$5,000,000 will be allotted to the several states for surveys and planning, \$5,000,000 to cover administrative expenses in carrying out plans that have been approved, and \$100,000,000 for the construction of hospitals and related facilities. Thereafter such sums for construction and administrative purposes will be authorized for each fiscal year as Congress may determine to be necessary.

ALLOTMENTS TO STATES

The sum to be made available for surveys and the development of programs will be allotted by the Surgeon General to the several states on the basis of their respective populations, financial needs and such other factors as he finds relevant. In connection with these allotments no specific provision appears in the bill for advice from the Federal Advisory Council. From these allotments each state will be entitled to receive, after an application has been approved, an amount equal to the "federal percentage," which will be determined in accordance with regulations made by the Surgeon General. "Such percentage shall be not less than 25 per centum or more than 75 per centum [presumably of the estimated cost of the survey and the development of the program] for any state, and within that range such percentage shall be determined for the several states on the basis of their relative financial needs."

The sum to be made available for construction and for administrative expenses will be allotted on the basis of the population and financial needs of the respective states and, in the case of allotments for construction of hospitals, the relative need for such construction, or, in the case of allotments for administrative expenses, on the basis of special administrative problems. The Surgeon General will be authorized to promulgate regulations under which these grants are to be made, but only on the recommendation of the Federal Advisory Council and after consultation with the state agencies designated in the several state plans. Grants to a particular state may be terminated whenever the Surgeon General finds, after affording reasonable notice and opportunity for a hearing, that there has been a failure substantially to comply either with any provision required to be included in the application for funds for surveys and the development of programs or in any construction plan, or with any regulation promulgated by the Surgeon General.

APPROVAL OF STATE APPLICATIONS AND PLANS

In order to obtain any of the federal money made available for surveys and for the development of construction programs, a state must make an application therefor to the Surgeon General. The application must (1) designate a single state agency as the sole agency to supervise the survey and to develop the program; (2) provide for the designation of a state advisory council to include representatives of nongovernmental organizations or groups and of state agencies concerned with the operation, construction or utilization of hospitals; (3) provide for compliance with standards prescribed by the Surgeon General with the approval of the Federal Advisory Council, and (4) provide that the state agency will make such reports, in such form and containing such information as the Surgeon General may from time to time require and comply with such provisions as he may from time to time find necessary to assure the correctness and verification of such reports. If an application complies with the foregoing requirements, the bill requires the Surgeon General to approve it.

Before a state may participate in any benefit from the distribution of federal money made available for construction programs and for administrative expenses, it must submit a state plan to the Surgeon General for approval. A state plan, to be

approved, must (1) designate a single state agency as the sole agency for the administration of the plan, or designate such agency as the sole agency for supervising the administration of the plan; (2) contain satisfactory evidence that the state agency designated will have authority to carry out such plan; (3) set forth a hospital construction program which the Surgeon General, on recommendation of the Federal Advisory Council, finds to be in accordance with standards prescribed by him with the approval of the Council, and to be sufficient, in conjunction with existing facilities, to provide the necessary physical facilities for furnishing adequate hospital, clinic and similar services to all the people of the state, and which, in the case of a state which has developed a construction program after making the required surveys, conforms to the program so developed; (4) set forth the relative need, determined in accordance with standards prescribed by the Surgeon General with the approval of the Federal Advisory Council, for the several projects included in the program, and provide for construction, so far as financial resources available therefor and for maintenance and operation make possible, in the order of such relative need; (5) provide such method of administration as the Surgeon General finds necessary for the proper and efficient operation of the plan, including provision for affording to an applicant for a construction project an opportunity for hearing before the state agency; (6) provide that the state agency will make such reports, in such form and containing such information, as the Surgeon General may from time to time require, and comply with such provisions as the Surgeon General may from time to time find necessary to assure the correctness and verification of reports, and (7) provide that the state agency will from time to time review its hospital construction program and submit to the Surgeon General and to the Federal Advisory Council any necessary modifications. If a state plan meets these requirements, it must be approved by the Surgeon General.

APPROVAL OF PROJECTS AND PAYMENTS FOR CONSTRUCTION

For each construction project contained in a state plan there must be submitted to the Surgeon General an application by a state or political subdivision or by a public or other nonprofit agency. Each application must set forth a description of the site for such project, detailed plans and specifications, reasonable assurance that the title to the site is or will be vested solely in the applicant and reasonable assurance that adequate financial support will be available for the construction of the project and for its maintenance and operation when completed. No application for a project may be approved by the Surgeon General unless its approval has been recommended by the state agency. The bill does not specifically require the Surgeon General to seek the advice of the Federal Advisory Council in passing on applications for projects.

If an application for a project is approved, the Surgeon General will certify to the Secretary of the Treasury an amount equal to the "federal percentage" of the estimated cost of the construction of the project, designate the appropriation from which it is to be paid and from time to time certify instalments to be paid on account. Certification of instalments will be made after such inspections and on such conditions designed to assure satisfactory completion of the project as the Surgeon General shall determine. Such certifications will provide for payments to the state, except that if a state is not authorized by law to make payments to the applicant the certification shall provide for payment to the applicant.

In determining whether to approve a project, in determining whether to certify an instalment and in any inspection authorized by the bill, the Surgeon General will as far as practicable utilize the services and advice of the Federal Works Agency in reviewing the title, working drawings and specifications of any project, supervising the awarding of contracts and inspecting the performance of the work.

CONFERENCES OF STATE AGENCIES

The Surgeon General will be authorized, in carrying out the provisions of the bill, to invite representatives of as many state agencies to confer with him as he deems necessary or proper. A conference of the representatives of all state agencies, however, must be called annually by the Surgeon General. If five

or more of such agencies request it, the Surgeon General must call a conference of representatives of all state agencies joining in the request.

PROMULGATION OF REGULATIONS

The Surgeon General is authorized to make such regulations and perform such other functions as he finds necessary to carry out the provisions of the bill. All regulations with respect to grants to states for administrative purposes in carrying out plans or for construction projects, however, may be promulgated only on recommendation of the Federal Advisory Council, as before noted, and after consultation with state agencies. The bill provides that, as far as practicable, the Surgeon General shall obtain the agreement of state agencies prior to the promulgation of any such regulations or amendments.

MISCELLANEOUS

A "public health center" within the meaning of this bill means a publicly owned facility for the provision of public health services and medical care, including related facilities such as laboratories, clinics and administrative offices operated in connection with public health centers. A "nonprofit hospital" is defined to mean any hospital owned and operated by a corporation or association, no part of the net earnings of which inures to the benefit of any private shareholder or individual. The money that is allotted to a state for construction purposes may not be expended for the cost of the acquisition of land, except in connection with the construction of public health centers. The bill defines the term "state" to include Alaska, Hawaii, Puerto Rico and the District of Columbia.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Bills Introduced.—H. R. 1442, introduced by Representative Miller of Nebraska, proposes an amendment to the Social Security Act under which federal assistance would be made available to the states to permit them to provide medical, surgical and hospital care to individuals eligible for old age assistance. Any state, it is proposed, may provide for such care either through the purchase of insurance or through the administration of a plan by or under the supervision of a state agency. H. R. 1571 and H. R. 1572, both introduced by Representative Dickstein, New York, propose respectively that no regulation prescribing the qualifications of the members of the Army and Navy nurse corps shall require as a condition for appointment the registration under the laws of any state. H. R. 1188, introduced by Representative Mott, Oregon, would authorize the Director of the Census to issue certifications of birth records. H. R. 1385, introduced by Representative Talbot, Connecticut, proposes that any blind person who is traveling on a train being operated by any common carrier by railroad subject to the Interstate Commerce Act may keep his seeing-eye dog with him in any coach or Pullman car of the train. H. R. 562, introduced, by request, by Representative Rankin, Mississippi, proposes to extend to all service connected disabled veterans in need thereof and feasible therefor eligibility for vocational rehabilitation under the laws administered by the Veterans' Administration. H. R. 1373, introduced by Representative McDonough, California, proposes a federal appropriation of \$2,600,000 for the construction of a marine hospital in or near Los Angeles and for the acquisition of a suitable site. S. 235, introduced by Senator Langer, North Dakota, proposes to prohibit the requirement of the taking of the so-called pauper's oath by certain veteran applicants for hospital treatment or domiciliary care. H. R. 710, introduced by Representative Dickstein, New York, declares it to be unlawful to alter or attempt to alter any part of the inner surface of one's own or any other person's hand or hands for the purpose of preventing identification by the use of fingerprints. H. R. 758, introduced, by request, by Representative Pace, Georgia, provides for the development of better diets and an improved nutritional status for the people of the United States. S. 330, introduced by Senator White, for himself and Senator Brewster, both of Maine,

and H. R. 587, introduced by Representative Smith, Maine, propose the creation of a Division of Water Pollution Control in the United States Public Health Service. H. R. 612, introduced by Representative Tolan, California, and H. R. 1411, introduced by Representative Angell, Oregon, propose to amend the Social Security Act to provide grants to the states for the physically disabled. H. R. 650, introduced by Representative Allen, Louisiana, provides that any person who served in the military or naval forces of the United States during a recognized campaign or expedition, who was honorably discharged from such service, shall be granted hospital and domiciliary care by the Veterans Administration subject to the same restrictions and limitations as are now applicable to World War veterans. H. R. 1289, introduced by Representative Peterson, Florida, proposes to authorize hospitalization of retired officers and enlisted men of the armed forces who are peacetime veterans. H. R. 1412, introduced by Representative Angell, Oregon, proposes to authorize the Secretary of the Interior to locate, establish, construct, equip and operate a hospital for the insane of Alaska. H. R. 1513, introduced by Representative Kilday, Texas, would provide dispensary treatment and hospitalization in Army and Navy hospitals for retired enlisted men, of the Army, Navy, Marine Corps and Coast Guard. H. R. 1581, introduced, by request, by Representative Rankin, Mississippi, would provide orthopedic and prosthetic appliances to veterans of any war discharged under conditions other than dishonorable.

STATE LEGISLATION

Arkansas

Bill Introduced.—H. 2 proposes to prohibit a county clerk from issuing a marriage license unless both applicants to the proposed marriage present a certificate of the state health department of any state showing that a blood test of the party has been made and that that test indicated freedom from syphilis in the active stage.

Indiana

Bill Introduced.—S. 37, to amend the workmen's compensation act, proposes, among other things, to require an employer to provide for an injured employee necessary first aid, medical and surgical services and all necessary medical and hospital services limited to that which is reasonably required to cure or relieve the effects of the injury for 180 days, unless the industrial board orders a longer period.

Maryland

Bills Introduced.—S. 66 proposes to prohibit the operation of a hospital without possessing a license to do so from the State Board of Health. The term "hospital" is defined in the bill to mean "any institution which maintains and operates facilities for the care and/or treatment of two (2) or more non-related persons as patients suffering mental or physical ailments." S. 86 to amend the law authorizing the formation and operation of nonprofit hospital service plans, proposes to permit the operation by one corporation of both medical and hospital service plans.

Massachusetts

Bill Introduced.—S. 86 proposes to provide cash sickness compensation for an employee who is unable to work because of sickness. Benefits are to be paid from a fund which is to be established by contributions from the employee of 1 per cent of wages paid him and by an equal contribution from the employer.

Minnesota

Bill Introduced.—H. 82 proposes to create a commission to select a site for the erection of another state school for the feeble-minded and to authorize the establishment of such an institution.

Montana

Bill Introduced.—H. 4 proposes as soon as practicable to establish a new state hospital for the insane and to utilize the facilities presently used for the state hospital for the insane to care for persons who by reason of age and infirmity require care and treatment but who are not actually insane.

Nebraska

Bills Introduced.—L. B. 46 proposes, in effect, to authorize an osteopathic practitioner to execute the physician's certificate as to freedom from venereal disease required with respect to each party to a prospective marriage as a condition precedent to issuance of license to marry. L. B. 47, to amend the medical practice act, proposes that two of the seven members of the board of examiners in medicine and surgery shall be graduates of an accredited school of osteopathy. L. B. 75, to amend the nursing practice act, proposes to prohibit a person from practicing as a registered nurse anesthetist unless possessing a license to practice nursing.

New York

Bills Introduced.—S. 94 and A. 98 propose to enact a separate chiropractic practice act and to create an independent state board of chiropractic examiners to examine and license applicants for licenses to practice chiropractic. The practice of chiropractic is defined as "the science of locating and the removing of nerve interference in the human body, according to chiropractic principles, where such interference is the result of or caused by misalignment or subluxations of the vertebral column. It excludes operative surgery, the reduction of fractures, the prescription or use of drugs or medicine, and the practice of obstetrics." A. 260 proposes to provide for the establishment and administration of a system of compulsory health insurance.

North Carolina

Bill Introduced.—H. 22 proposes that in an action to determine the paternity of a child the court may order the defendant, the mother and the child to submit to a blood grouping test and to make the results of the blood grouping test admissible in evidence when offered by a duly licensed practicing physician.

Oklahoma

Bill Introduced.—H. 81 proposes to prohibit a county clerk from issuing a license to marry unless each party to the proposed marriage files a certificate signed by a licensed physician that the party is free from any venereal disease.

Oregon

Bills Introduced.—S. 3 proposes to authorize the state board of control to establish and operate in Multnomah County a hospital for the mentally diseased if the electorate of the state approve in a referendum provided for in the bill. H. 20, to amend the workmen's compensation act, proposes to provide compensation for a hernia if the injured workman proves that the hernia was the result of strain or injury arising out of and in the course of employment. The present law requires the worker to prove that the hernia was immediately preceded by an accident arising out of and in the course of employment.

Pennsylvania

Bill Introduced.—S. 18, to amend the law regulating the sale of stated hypnotic, analgesic and weight reduction drugs, proposes to add to the drugs so embraced "Amphetamine (Benzedrine) and Thyroid." Such drugs can be sold at retail only on the written prescription of a licensed physician, dentist or veterinarian.

South Dakota

Bill Introduced.—H. 21 proposes apparently to add to the act regulating the operation of county hospitals a provision that prohibits the board of trustees of such a hospital and its management from discriminating between practitioners of the various healing arts and to confer on every duly licensed doctor of medicine and osteopathic "physician" the right to practice in said county hospital.

Tennessee

Bills Introduced.—S. 96 and H. 158, to amend the naturopathic practice act, proposes to require an applicant to practice naturopathy to have graduated from a four year high school course, to have completed two years' actual attendance at an accredited college and to have completed courses in general inorganic chemistry, organic chemistry, biology and physics before entering the school where he obtains his "professional" education.

Texas

Bill Introduced.—S. 29 proposes to enact a communicable disease control act which, among other things, (1) defines a communicable disease as any disease that may be transmitted from one person or animal to another person or animal either directly or indirectly; (2) requires physicians to report cases of reportable communicable diseases to designated health authorities; (3) authorizes the establishment of quarantine under the circumstances stated, and (4) states specific control measures for designated reportable diseases.

Utah

Bills Introduced.—S. 6 proposes to authorize the establishment and operation by the state of a hospital for poliomyelitis and children's diseases. S. 7 authorizes the establishment and operation of local full time county, city-county and/or district health departments. S. 23 proposes to permit the county commissioners to authorize the admittance to any county hospital of private patients who are financially able to pay for the cost of care and maintenance at that hospital. S. 26 proposes to prohibit, without a license from the state department of health, the operation of a maternity hospital or place of any kind in which prepartum or postpartum care is rendered. S. 27 proposes to authorize the state board of health to make and enforce rules and regulations providing for the reporting of occupational diseases.

Washington

Bills Introduced.—S. 6 proposes to authorize the establishment and operation of a medical and dental school at the University of Washington and to appropriate \$450,000 for such purpose. H. 13 proposes to make it unlawful for any person, corporation, partnership or association to dispense or sell any lenses for the purpose of correcting or aiding vision except on the prescription of a duly licensed physician or optometrist.

Washington Letter

(From a Special Correspondent)

Jan. 22, 1945.

Request for Medical Insurance Is Renewed

The Social Security Board, in presenting its program for "cradle to grave" social security today, renewed its request for medical insurance. The board's annual report said that medical insurance could be introduced without socializing medicine or regimenting physicians. It pointed out that, despite a common belief that the United States is the world's healthiest nation, other countries have lower death rates and higher life expectancy rates. The board's proposals, expected to incorporate President Roosevelt's forthcoming recommendations to Congress, are substantially the same as those made a year ago. They ask for broadened coverage of old age and survivors' insurance, liberalized unemployment benefits and establishment of medical and disability insurance. Given little attention by Congress last year, they are expected to get further this year, since both political parties urged broader social security coverage during the election campaign. Advocating a system of disability insurance, the report stated that an average of seven million persons were sick or disabled on an average working day. In its request for a system of insurance to prepay the costs of medical and hospital care, the board said that it "disavowed" socialized medicine and "regimentation" of physicians. It said that these "much advertised fears" were "wholly groundless." The board said that the principal reason for the lack of medical care is the present method of paying for it.

Army Would Commission Nurses as Lieutenants

The Army "never had the slightest intention of drafting nurses as privates but will commission them as second lieutenants, whether or not they volunteer," Surg. Gen. Norman T. Kirk told a hearing of the House Military Affairs Committee. He urged an immediate nurse draft, declaring that he was convinced that appeals for volunteers would not bring in the 20,000 nurses needed by June to meet the 270 per cent increase in overseas casualties. General Kirk revealed that the Army is returning 30,000 to 32,000 overseas casualties each month to American hospitals. Last year 8,500 were returned monthly. Furthermore, only 15,000 leave the hospitals each month. Between

May and December of 1944, when 27,000 nurses graduated from hospital schools, only 2,000 nurses volunteered for the Army Nurse Corps, he said. General Kirk said that only 2 per cent of all volunteers had been turned down for not meeting requirements. Every Negro nurse who applies and meets requirements will be accepted, he stated. Male nurses, however, will still not be commissioned in the nurse corps but will have an opportunity to become medical administrative corps officers.

Probe of Veteran Neuropsychiatric Problem Urged

Increased attention is being given here to the problem of the discharged war veteran afflicted with a neuropsychiatric condition as a result of war service. It has been suggested that an overall investigation of veterans' affairs might help to focus attention on this as well as on other aspects of treatment of the returning war veteran. A coordinating agency has been proposed to bring together the activities relating to veterans now being handled separately by the Veterans Administration, the Federal Security Administration, which has state rehabilitation offices, the U. S. Employment Service, the U. S. Bureau of Education, Selective Service, the U. S. Public Health Service and the War and Navy departments. One major difficulty with regard to treatment and restoration of neuropsychiatric veterans is the lack of trained psychiatrists. It was suggested that the G I Bill of Rights provide for their training.

Abolition of Nation's Slums Recommended

Congress has received an estimate from the American Institute of Planners that it would cost 12 to 15 billion dollars to buy up and demolish America's blighted areas. The information came in testimony of Alfred Beltman before the Senate Subcommittee on Postwar Economic Policy. He urged that the federal government back such a program, financed with 750 million dollars a year, which might eventually cost the government nothing under a plan whereby the future yield from redeveloped areas would repay the Treasury.

Soviet Clears Way for UNRRA Supplies

The Soviet Union is clearing the way for shipments of United Nations Relief and Rehabilitation supplies to Poland and Czechoslovakia, according to announcement here of Herbert H. Lehman, director general. He said that the Soviet Union has advised UNRRA that Black Sea port reception facilities and inland transport for food, clothing, medical supplies and other relief goods would be available. Mr. Lehman said it would now be possible to make the first shipment of relief supplies to these two liberated countries.

Official Notes

DOCTORS LOOK AHEAD

The American Medical Association and the National Broadcasting Company are presenting the twelfth consecutive season of nationwide network health broadcasts weekly from January 6 to June 30, 1945. Included in the series are broadcasts relating to wartime and postwar developments, with special emphasis on medical progress of the present day and what it foreshadows for the nation's health in the immediate future.

Topics in the series, which is called Doctors Look Ahead, will be announced weekly in THE JOURNAL and monthly in *Hygeia*. Fast moving events may, however, cause last minute substitutions. Local newspapers should be consulted for announcements of time and stations. The program will be broadcast each Saturday at 4 p. m. Eastern War Time (3 p. m. Central, 2 p. m. Mountain and 1 p. m. Pacific War Time). When conflicts exist with local programs, rebroadcast may be arranged at hours other than on the network schedule. The next three topics are:

January 27. Penicillin (Dr. Austin Smith).
February 3. Social Hygiene.
February 10. Heart Disease (Dr. Edwin P. Jordan).

The broadcast will be under the supervision of the Bureau of Health Education, whose director, Dr. W. W. Bauer, will summarize each program except when another speaker is announced.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

New Head of Industrial Hygiene.—Irving R. Tabershaw, surgeon, U. S. Public Health Service Reserve, assigned to the division of occupational hygiene, Massachusetts Department of Labor and Industries, Boston, has been assigned to the Alabama Department of Public Health to serve as director of the division of industrial hygiene, Birmingham, effective January 1. Dr. Tabershaw succeeds Dr. George A. Shipman.

CONNECTICUT

Campaign for Society's New Home.—Pledges and gifts are now being received by the Connecticut State Medical Society in its campaign for \$50,000 to defray the cost of a new home for the society.

Society News.—Drs. James R. Miller and Clinton D. Deming, both of Hartford, were chosen president and secretary, respectively, of the New England Surgical Society at its recent annual meeting.

DELAWARE

Society News.—Dr. Thomas Nelson Carey, associate professor of medicine, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, discussed "Rocky Mountain Spotted Fever" before the New Castle County Medical Society of Delaware, January 16, in Wilmington.

ILLINOIS

Fellowship Created for Dr. Stolp.—A medical fellowship has been established at the Evanston Hospital, Evanston, in memory of the late Dr. Rufus B. Stolp, Wilmette, who was for many years chief of the medical staff of the contagious department of the hospital. The fellowship will support a research project at the hospital each year. Dr. Stolp was formerly a resident of Kenilworth and was one of the founders and first president of the Kenilworth Historical Society. He died Nov. 3, 1942.

Chicago

Grants to Illinois.—The University of Illinois College of Medicine recently received a grant of \$23,000 from the Field Foundation for a study in allergy and an anonymous gift of \$20,000 for visual aid studies.

Conference on Rehabilitation Canceled.—The Midwest Conference on Rehabilitation of the Institute of Medicine of Chicago, scheduled to be held February 12, has been canceled. The sixth Frank Billings Lecture of the Thomas Lewis Gilmer Foundation of the institute is also canceled. The lecture was to be given the evening of February 12 at the Drake Hotel by Col. Howard A. Rusk, M. C., chief, convalescent training division, Office of the Air Surgeon.

Administrative Changes at University of Chicago.—Among the recent changes in the Division of Biological Sciences, including the University of Chicago School of Medicine, are the appointment of Dr. William H. Taliaferro, Eliakim Hastings Moore distinguished service professor of parasitology, as adviser to the president in the biological sciences. The deanship vacated by Dr. Taliaferro has been assumed by Roland W. Harrison, Ph.D., professor of bacteriology, who has been acting dean of the Division of Biological Sciences. Dr. Arthur C. Bachmeyer, will continue as associate dean of the division and director of the university clinics, spending part time until 1946 as director of study for the Commission on Hospital Care. Science reports that Dr. Basil C. H. Harvey, acting dean of students of the division, including the school of medicine, during the past year, has retired. F. Joseph Mullin, Ph.D., assistant professor of physiology, has been appointed assistant dean of students, pending the appointment of a dean.

Medical Alumni Group Reorganized at University of Chicago.—The *Bulletin of the Alumni Association* of the University of Chicago School of Medicine has just made its appearance as a new feature of the general reorganization of the medical alumni group that has been under way for several months. Another new feature is the creation of a senate which

will serve as the ruling body; it is composed of the officers, representatives of all classes that have graduated at the medical school, the junior and senior classes, the editorial board of the Yearbook, which was published for the first time in 1944 (THE JOURNAL, June 10, 1944, p. 439), and representatives of the faculty. The Medical Alumni Association has been relatively inactive for a number of years; the creation of the senate body, with its broadening powers for development and its plan to hold quarterly meetings will promote a well coordinated program of alumni activity. At the first meeting of the senate at the Quadrangle Club, January 18, Mr. Charlton Beck, executive secretary of the Alumni Association of the University of Chicago, was made an honorary member of the Medical Alumni Association and presented with the first key to be awarded by the group. Officers of the Medical Alumni Association include Drs. Victor Johnson, Secretary of the Council on Medical Education and Hospitals of the American Medical Association and professorial lecturer in physiology at the university, president; Joseph Alfred Rider, now serving an internship at Presbyterian Hospital, vice president; John V. Prohaska, treasurer, and Hilger H. Jenkins, associate professor of surgery at the university, secretary.

INDIANA

Personal.—Frank S. Stafford, M.S., director of the division of health and physical education, Indiana State Board of Health, has been given a leave of absence until July 1, 1945 to go to Washington to head the physical fitness program under the United States commissioner of education, John W. Studebaker.—Dr. Harry P. Ross, president of the Richmond Board of Health, has been appointed a member of the state board of health to fill the unexpired term of the late Dr. Henry C. Metcalf.

New Department of Preventive Medicine.—Dr. Gerald F. Kempf, head of the communicable disease service at the Indianapolis City Hospital, has been appointed superintendent of preventive medicine in the Indianapolis City Board of Health, effective January 1. The position is a new one and is the beginning of an expanded program of public health education. In his new capacity Dr. Kempf will also serve as assistant to Dr. Herman G. Morgan, secretary of the city board of health.

Lectureship Created for Dr. Barnhill.—A lectureship has been established at the Indiana University School of Medicine, Indianapolis, by Phi Delta Upsilon in memory of the late Dr. John Finch Barnhill, for many years connected with the university in the department of otolaryngology and head surgery. A plaque will be hung in the medical school on which will be placed each year the name of the freshman medical student who has done the most outstanding work in anatomy. The name of Maurice A. Turner, Indianapolis, a freshman student of last year, is the first name to be placed on the plaque.

Secretaries' Conference.—The Indiana State Medical Association held its annual Secretaries' Conference at the Claypool Hotel, Indianapolis, January 21. Among the speakers were:

Mary Walsh, educational director, state board of examination and registration of nurses, Indianapolis, The Bolton Law and Its Relationship to the Patient.

Don C. Hawkins, special agent, American Health Insurance Corporation, Chicago, Group Malpractice Insurance and Health and Sickness Insurance.

Dr. John D. Van Nuys, medical director, Indiana University Medical Center, Indianapolis, Children's Bureau Program.

Drs. Norman M. Beatty and J. William Wright, co-chairmen, Committee on Public Policy and Legislation, state medical association, Indianapolis, Legislative Program.

Dr. John H. Fitzgibbon, Portland, Ore., chairman, American Medical Association Council on Medical Service and Public Relations.

Dr. Orley E. Wilson, secretary, Elkhart County Medical Society, Elkhart, How Local Societies are Meeting Present Emergencies.

Lieut. Col. Harold C. Lueth, Surgeon's General Liaison Officer to the American Medical Association, Future Trends in Medical Practice.

Dr. Eldridge M. Shanklin, Hammond, editor, *Journal of the Indiana State Medical Association*.

At the dinner session the speakers were Drs. Nelson K. Forster, Hammond, president, state medical association, and Walter H. Judd, congressman, Minnesota, on "Problems Facing the New Congress and the American People."

MARYLAND

Exhibit of Medical Art.—A collection of the work of the late Max Brödel is the focal point of interest in a display of medical art at the Enoch Pratt Free Library, Baltimore, which opened January 8 and will continue through January 29. The collection was lent by the department of art as applied to medicine, Johns Hopkins University School of Medicine.

Other exhibitors include the daughter of Professor Brödel, Elizabeth Brödel, now with New York Hospital; Tom Jones, head of the department of art, University of Illinois, and Mr. Willard C. Shepard, art editor, W. B. Saunders Company, Philadelphia.

Association of Private Practicing Psychiatrists.—On December 5 the Baltimore Association of Private Practicing Psychiatrists was organized to investigate the problems of private psychiatric practice in the community. Members of a preliminary planning committee are Drs. Wendell S. Muncie, chairman, Horace K. Richardson and Robert V. Seliger. In announcing the creation of the society, which stemmed from the increased work thrown on the practicing psychiatrist, it was stated that a group was needed both to pool thoughts, opinions and feelings relative to dynamics, psychotherapy, mental hygiene, the practical items of hospital and extramural treatment facilities, community education and medical economics, and from this to bring out the second point, constructive results and the development of the foregoing plus consideration and methods of having certain psychiatric patients admitted to general hospitals, and conference meetings with the heads of the city and state full time mental hospital systems. The group is interested in having similar groups and opinions from other cities throughout the country. Those physicians who are interested should communicate with Dr. Muncie, 11 East Chase Street, Baltimore.

MICHIGAN

Personal.—Thomas L. Patterson, Ph.D., since 1941 research professor of physiology, Wayne University College of Medicine, Detroit, recently received the honorary degree of doctor of science from Clark University, Worcester, Mass., in recognition not only of "his contributions through teaching and research but also in his human relationships; eminent for his research work and numerous publications in the field of his chosen science, physiology; a devoted student of the problems pertaining to human health."

Joint Project for Care of Expectant Mothers.—The Wayne County Medical Society and the Detroit Department of Health are cooperating in a program of group discussion and demonstration for the expectant mother. The physician may refer patients to a series of classes in antepartum education including bath demonstration, infant clothing and general child care. Admission to the classes will be by card signed by the attending physician. The discussion will be directed by qualified nurses under the supervision of the medical society, and material for demonstrations will be furnished by the society. The conferences started at the David Whitney House, January 17, and will be held weekly.

Miner Memorial Fund.—A \$10,000 scholarship fund for medical students has been established at Wayne University by Mrs. Marion M. Leahy and Helen I. Miner as a memorial to their father, the late Dr. Stanley G. Miner. Born in Detroit in 1861, Dr. Miner was a graduate of the Wayne University College of Medicine, Detroit, and served on its faculty as professor of otology, laryngology, rhinology and physical diagnosis. He also was a member of the staff of St. Mary's Hospital and was at one time chief of staff for that institution. From 1913 to 1919 he was a member of the Detroit Public Welfare Commission and was actively interested in the establishment of Receiving Hospital. He died June 28, 1942.

MINNESOTA

Journal-Lancet Lecture.—Brig. Gen. James S. Simmons, chief of the division of preventive medicine, Office of the Surgeon General, delivered the fourth annual Journal-Lancet Lecture Dec. 7, 1944 at the University of Minnesota Medical School, Minneapolis. His subject was "Recent Advances in the Control of Insect Borne Diseases."

Proposed Industrial Health and Efficiency Committee.—The University of Minnesota Medical School, Minneapolis, has announced its plan to create an industrial health and efficiency committee to assemble and coordinate the activities of the school in industrial medicine and to devise ways and means of making immediately available to industry discoveries and developments in this field. At a recent meeting at which Dr. Harold S. Diehl, dean of medical sciences at Minnesota, announced plans for the Mayo Memorial (THE JOURNAL, January 13, p. 111), consideration was given to the relationship and value of the memorial to the industries of the state, this point having been discussed at a previous meeting of the committee of founders of the memorial. The creation of the industrial health and efficiency committee was believed the best step in developing a coordinated program at the university

to ensure a comprehensive and well regulated development of research teaching programs and other matters incidental to industrial health and medicine. It was proposed that the committee consist of the heads of the departments of the school of medicine most immediately concerned with the program.

License Suspended.—On Nov. 10, 1944 the Minnesota State Board of Medical Examiners suspended for a period of three years the license to practice medicine formerly held by Dr. Milton C. Wolf, who was associated for many years with the Heidelberg Medical Institute, St. Paul, and which in recent years has been known as the Mid-West Clinic. Dr. Wolf's license was suspended following a complaint that he had obtained \$74 in advance from a 26 year old male patient who had gone to Dr. Wolf complaining of pain in the lower part of his back. The patient testified at a hearing before the Minnesota State Board of Medical Examiners that he was questioned at length by an unlicensed associate of Dr. Wolf's in reference to sexual matters and lost manhood, notwithstanding the fact that the patient stated that he had been employed for four and one-half years in a foundry and had injured his back. The patient further testified that he was advised that the usual charge was \$150 as a down payment and \$5 per week for treatments but that in his case the charge would be only \$100 plus the charge for weekly treatments, and a guaranty "that he would be a man again." During the investigation by Mr. Brist on behalf of the Minnesota State Board of Medical Examiners, the money was returned to the patient. Dr. Wolf was born in Chicago in 1876 and graduated at the College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, in 1898. He was licensed in Minnesota in 1905 by examination. Dr. Wolf previously had been warned by the state board of medical examiners with respect to his practice at the Heidelberg Institute and the Mid-West Clinic.

NEBRASKA

Ninety-Six Years of Age.—Dr. James K. Newman, Omaha, observed his ninety-sixth birthday, January 5. Dr. Newman graduated at the Universidad Nacional Facultad de Medicina, Mexico, D. F., in 1879.

Dr. Joslin Gives Alpha Omega Alpha Lecture.—Dr. Elliott P. Joslin, professor emeritus of clinical medicine, Harvard Medical School, Boston, delivered the annual address before the Alpha Omega Alpha chapter of the University of Nebraska College of Medicine, Omaha, January 18, on "Diabetes Today."

NEW JERSEY

Hospital Restricts Employment of Private Nurses.—To help increase the supply of nurses available for military service, the board of managers of St. Elizabeth Hospital, Elizabeth, on January 3 restricted the employment of private nurses. In a statement to the press it was stated that the hospital would not assign any nurses under 45 years of age to private duty unless they were mothers of children under 14 or had been found unfit for military service.

NEW YORK

Graduate Lecture.—Dr. William Goldring, associate professor of medicine, New York University College of Medicine, will address the Nassau County Medical Society, Rockville Centre, February 27, on "Hypertension and Hypertensive Heart Disease."

Forum on Rabies.—To give the public a truer knowledge of the nature of rabies and its common methods of transmission and possible means of control, the Westchester County Medical Society held a forum on rabies January 17 at the County Center in White Plains. The speakers were Dr. James E. Perkins, Albany, director, division of communicable diseases, state department of health, and James E. Assing, formerly veterinarian for the New York City Health Department, engaged in rabies control and eradication.

Secretaries Named for State Society.—Dr. Walter P. Anderton, a practicing physician in New York since 1913 and assistant professor of clinical medicine at Columbia University College of Physicians and Surgeons, was appointed secretary of the Medical Society of the State of New York at a meeting of the society's council, January 11. He succeeds the late Dr. Peter Irving. Dr. Anderton graduated at Columbia in 1911. He received his license to practice in New York in 1913. Dr. Robert Roger Hannon, formerly assistant professor of medicine, Albany Medical College, and secretary of the state board of medical examiners, Department of Education, Albany, has been named executive officer of the Medical

Society of the State of New York, with offices in Albany. He fills the vacancy that occurred when Dr. Joseph S. Lawrence joined the staff of the American Medical Association, with offices in Washington, D. C. Dr. Hannon graduated at Johns Hopkins University School of Medicine, Baltimore, in 1919 and subsequently has served on the staffs of Johns Hopkins, Cornell University Medical College, University of Rochester School of Medicine and Dentistry and the Peiping Union Medical College, Peking, China.

New York City

Dr. Bristol Resigns as Executive Director of Hospital Council.—Dr. Leverett D. Bristol has resigned as executive director of the Hospital Council of Greater New York because of ill health. Prior to his appointment to this position (*THE JOURNAL*, Nov. 27, 1943, p. 850) Dr. Bristol served as health director of the American Telephone and Telegraph Company. Dr. Bristol is a member of the Council on Industrial Health of the American Medical Association.

Personal.—A silver vase was presented at a dinner to Dr. Howard W. Neal, Jamaica, who retired recently after thirty-five years as a medical examiner in Queens County. The presentation was made by Dr. L. Howard Moss, Richmond Hill, member of the medical board and of the board of trustees of Jamaica Hospital, where Dr. Neal had worked since his internship in 1909. He was chief of the hospital's department of gynecology and was recently retired with the title gynecologist emeritus.—Dr. Robert C. Darling has been appointed associate professor of medicine at Columbia University College of Physicians and Surgeons.

The Future of the American Family.—A symposium on "The Future of the American Family" was held at the Waldorf-Astoria Hotel, New York, January 23 (*THE JOURNAL*, January 20, p. 175) under the auspices of the American Education Fellowship, Child Study Association of America, Editors of the Survey Publications, National Child Labor Committee, National Committee for Mental Hygiene, National Committee on Housing, National Council of Negro Women, National Council for Parent Education and the Planned Parenthood Federation of America. The major federal agencies concerned with the family and other national voluntary agencies cooperated in providing discussion material for the symposium program.

Eye Examinations Start Union Health Plan.—With \$2,924,000 collected since May, a health and vacation fund for 80,000 dressmakers in New York and vicinity began operation January 3 with an eye examination given to 150 employees of the Apex Dress Company by physicians and assistants from the union health center. All workers will receive examinations in the 2,215 shops of the industry. Workers with defective vision will be referred to the health center for further medical treatment, and corrective treatment and eyeglasses will be furnished free of charge. The eye program will be a part of the health conservation and sickness benefit plan established under the health fund. The *New York Times* reports that hospitalization, medical service, illness disability benefits and aid to workers suffering from tuberculosis are to be developed. With the health program will be combined free vacations with payments of \$23 to \$38 to cover a week away from work. The fund was created eight months ago in the collective agreement between the dressmakers union and the four employer associations in the industry.

OHIO

State Meeting Canceled.—The Ohio State Medical Association announced on January 16 that the ninety-ninth annual meeting of the Ohio State Medical Association, which had been scheduled to be held in Columbus, May 1-3, has been canceled.

Radio Series on Health.—The Cleveland Health Museum, in cooperation with the Cleveland Dental Society, the Academy of Medicine of Cleveland and the Cleveland Mental Hygiene Association, began a new series of radio lectures over Station WGAR, December 12, with a talk by Dr. Henry C. Schumacher, director of the Cleveland Guidance Clinic, on "Your Mind and You." Others in the series include:

- Calvin O. Fritz, D.D.S., and class, Western Reserve University, Triumph Over Pain, December 19.
- Mrs. James D. Polley, Family Health Association, The Parent and the Happy Child, December 26.
- Dr. James J. Slowe, Vitamins: Their Use and Abuse, January 2.
- Bertha M. Luckey, Ph.D., board of education, Guiding Teen Age Youth in Home and School, January 9.
- Dr. Frank F. Tallman, commissioner of mental diseases, Columbus, Better Mental Health for Ohio Citizens, January 16.
- Dr. Richard E. Stout, Worry and Nervous Tension, January 23.
- Dr. Joseph L. Fetterman, What the Community Can Do to Aid Returning Servicemen, January 30.
- Francis A. Arnold, D.D.S., U. S. Public Health Service, Tooth Decay Can Be Controlled, February 6.

OREGON

Personal.—Dr. Wilmot C. Foster, Portland, has been appointed by the governor as a member of the state board of medical examiners to fill the vacancy that occurred with the death of Dr. Harold L. Blosser.

Noble Wiley Jones Honored.—On December 14 the Portland Academy of Medicine, at its annual dinner meeting at the Heathman Hotel, honored Dr. Noble Wiley Jones, who has practiced in Portland since 1907, for his years of service to the academy. Dr. Laurence Selling, professor of medicine and neurology, discussed his contribution to scientific medicine. Dr. Homer P. Rush, associate clinical professor of medicine to the practice of medicine, and Olof Larsell, Sc.D., professor of anatomy, to medical education. All are members of the faculty of the University of Oregon Medical School, Portland. Dr. Jones is a member of the committee appointed to form the Medical Research Foundation sponsored by the Portland Academy of Medicine and designed to aid medical research in the vicinity and a member of the library committee of the academy and of the medical school. He has served as secretary and president of the Portland Academy of Medicine.

TEXAS

Physician Honored with Gift for New Hospital.—A charter and war bonds to use as payment for the erection of the first wing of a hospital in Grand Saline was given to Dr. V. Bascom Cozby at a meeting of the local Lions Club recently. Mr. E. B. Germany, oil operator in Dallas and a native of Grand Saline, is the donor of the gift. When completed the hospital will be known as the Cozby-Germany Hospital.

University News.—The National Live Stock and Meat Board of Chicago has donated \$7,200 to the University of Texas Medical Branch, Galveston, for the support of work in fat metabolism under the direction of Dr. Arild E. Hansen, professor of pediatrics and director of the child health program. The work of the child health program is supported by the William Buchanan Foundation of Texarkana. A grant of \$1,800 has been made by the Abbott Laboratories of Chicago to the department of internal medicine at the medical school to support research work of Dr. Charles T. Stone, professor of internal medicine.

UTAH

Changes in the Faculty.—Dr. A. Cyril Callister, dean of the University of Utah School of Medicine, Salt Lake City 1, has announced the following changes in the faculty:

Dr. Francis D. Gunn, formerly associate professor of pathology at Northwestern University Medical School, Chicago, appointed professor and head of the department of pathology (*THE JOURNAL*, Aug. 26, 1944, p. 1201).

Dr. Hans Hecht, formerly instructor in medicine, Wayne University College of Medicine, Detroit, appointed instructor in medicine.

Dr. Louis S. Goodman, professor of pharmacology at University of Vermont College of Medicine, Burlington, appointed professor of pharmacology and chairman of the department of pharmacology and physiology.

James E. P. Tomlin, Ph.D., instructor in pharmacology and physiology at the University of Vermont College of Medicine, appointed assistant professor of physiology.

Corrine Manuel, P.S., M.T., appointed research assistant in the department of pharmacology.

Abbott Laboratories, North Chicago, Ill., has made an additional grant of \$1,500 to Dr. Goodman for the study of new anticonvulsants and analgesic compounds. The Gravidan-Delawanna, Inc., New York, has made a grant of \$16,000 to Dr. Goodman to be expended over a period of two years for the purpose of investigating a large series of new organic compounds for their pharmacodynamic properties and therapeutic actions.

WASHINGTON

Hospital News.—A \$350,000 addition is being constructed at St. Elizabeth's Hospital, Yakima. The addition is four stories high with a bed capacity of 50 and will contain, among other things, an isolation department, physical therapy room and a psychiatric ward.—Dr. Stanton A. McCool Jr., newly appointed health officer of Elma, has purchased the Elma General Hospital.

Portrait of Dr. Ward.—Ceremonies were held recently to unveil the portrait of Dr. Charles Byron Ward and to mark its presentation to the King County Medical Society. In making the presentation Dr. Homer D. Dudley, Seattle, reviewed the career of the late Dr. Ward, to whom goes the credit for the development of the King County Society Library which, while established in 1898, took on new status in 1931 when Dr. Ward arrived in Seattle and became interested in it. Until 1936 the library had been supported by

private subscription, and Dr. Ward is credited with the adoption of a by-law by the county medical society assessing each of its members \$10 a year for its support. Dr. James E. Hunter, Seattle, accepted the portrait, the work of Mr. Neale Ordayne, which will hang in the library, on behalf of the medical society.

WEST VIRGINIA

Changes in Health Personnel.—Dr. Elias W. Langs, U. S. Public Health Service Reserve, former district health officer for Norfolk and Princess Anne counties, Va., has been appointed acting director of the division of communicable diseases, state health department, to succeed Dr. Albert M. Price, Charleston, resigned. Dr. James T. Duncan, director of the bureau of tuberculosis, has been serving as acting director of the division of communicable diseases since September 1944.—Dr. Martin B. Woodward, director of the division of vital statistics, state health department, has resigned and is now on the staff at the Washoe County General Hospital, Reno, Nev. No successor has yet been appointed.

GENERAL

O. M. Goodloe Joins American Red Cross.—Dr. Ollie M. Goodloe, Lexington, Ky., formerly assistant director, bureau of county health work, for the Kentucky State Department of Health and recently deputy director of the Peoria Health Department, Peoria, Ill., has been appointed medical director of the eastern area of the American Red Cross.

Examinations for Technicians.—The American Orthoptic Council announces that its next examination will be held in September and October. The written examinations will be held at various cities in the country on Friday, September 7. Only those passing the written examinations will be permitted to take the oral and practical tests, to be given in Chicago on Saturday, October 6. Applications on official forms must be received before July 1. Address the American Orthoptic Council, 23 East 79th Street, New York 21.

The American Woman and the American Home of Tomorrow.—The Woman's Foundation has announced a conference to be held at the Westchester Country Club in Rye, N. Y., March 1-5, the theme of which will be "The American Woman and the American Home of Tomorrow." The foundation was granted a charter under the laws of Missouri, March 6, 1942 as a nonprofit organization, sponsored by the board of Stephens College, Columbia, Mo., and under the direction of a board of trustees. Under the provisions of its charter the foundation will engage in "the study of problems of the American home and of the American woman who must, in the home, face and deal with those problems of a practical, educational, cultural, moral and religious nature which vitally affect the health, efficiency, character and citizenship of the American people."

One Hundred Years of Pharmacy.—Sharp & Dohme, Inc., Philadelphia, is this year observing its one hundredth anniversary. The growth of the firm stemmed from a drugstore at Pratt and Howard streets, Baltimore, opened in 1845 by Alpheus Phineas Sharp, Winchester, Va., who three years earlier was the first graduate of the Maryland College of Pharmacy. In 1852 Mr. Sharp employed an apprentice, Louis Dohme, who did odd jobs around the store and in between times attended the Maryland College of Pharmacy, where he graduated in 1857. In 1860 he was made a partner, and the firm name was changed to Sharp & Dohme. A younger brother of Louis Dohme, Charles, who graduated at the Maryland College of Pharmacy in 1862, later joined the firm, and his son, Alfred R. L. Dohme, Ph.D., Baltimore, later became head of the company and is still a director.

Schering Awards to Medical Students.—Announcement of winners in the Schering award competition, open to undergraduate medical students in the United States and Canada, has been made by the committee of judges. Choosing from a large number of manuscripts on the subject "Hormones and Cancer," the committee has made the following awards:

First Prize, \$500, Maurice L. Silver, class of 1945, Loyola University School of Medicine, Chicago.

Second Prize, \$300, Sidney L. Kafka, class of February 1945, Middlesex University School of Medicine, Waltham, Mass.

Third Prize, tie, duplicate awards of \$200 each to Roslyn Wiener, class of 1945, University of Michigan Medical School, Ann Arbor, and Norman B. Hirt, class of 1945, Queen's University Faculty of Medicine, Kingston, Ont.

The Schering award competition has been offered annually by the Schering Corporation for the purpose of stimulating a current interest in endocrinology among undergraduate medical students. It is sponsored and administered by a special committee of the Association of Interns and Medical Students.

Nutrition Grants.—Grants of \$127,750 for research projects in nutrition were approved at the recent annual meeting of the board of trustees of the Nutrition Foundation in Minneapolis. Since its organization by food and related manufacturers in 1942 the foundation has made appropriations of \$654,700 to support ninety-five separate research projects in American universities. Total contributions of \$1,524,500 have been made to carry on the work of the nutrition foundation by fifty food and related manufacturers. Fourteen of the recently approved grants are for the extension of studies that have already been started by the foundation and have yielded results that have made it seem wise to extend the work from two to three years. New grants included one to Harvard University, Cambridge, Mass., for research in community nutrition, one of a series of similar studies to be initiated in different parts of the country to obtain information correlating nutrition and health. Other new grants are:

University of Chicago, Chicago, the iron requirement of the adolescent girl.

University of Southern California, Los Angeles, the intermediary metabolism of carotene.

Duke University, Durham, N. C., nature of the ascending paralysis produced in dogs on a B complex deficient diet and responding to biotin therapy.

Meharry Medical College, Nashville, Tenn., studies on pantothenic acid.

FOREIGN

Society News.—Dr. Andrew Fergus Hewat was reelected president of the Royal College of Physicians of Edinburgh recently. Drs. Lewis H. F. Thatcher, Alexander Ninian Bruce, David M. Lyon, William D. D. Small, William A. Alexander and David K. Henderson were elected to form the council for the ensuing year, and Dr. Lyon was nominated vice president.

American Scientists Aid Egyptians.—Dr. Maurice L. Tainter, director of research, and Chester M. Suter, Ph.D., director of chemical research of the Winthrop Chemical Company, Inc., Rensselaer, N. Y., and New York City, have arrived in Cairo to assist in new research on tropical diseases on invitation of the Egyptian government. The two American scientists will spend several months abroad investigating malaria, schistosomiasis, and a liver infestation and trachoma. As official guests of the Egyptian government, Drs. Tainter and Suter will join Egyptian scientists and medical men in collaborative efforts looking toward the development of clinical and laboratory facilities for a systematic and long range study of tropical diseases. Dr. Tainter has been associated with Winthrop since May 1943, having previously been professor of pharmacology, Stanford University School of Medicine, San Francisco. Prior to his association with Winthrop in October 1942 Dr. Suter was professor of organic chemistry at Northwestern University, Evanston, Ill., and chairman of its department of chemistry.

Artificial Tropical Climate Aids Rheumatic Fever.—About 20 patients have been treated with good results in a special "tropical ward" at the University Hospital of Lund in South Sweden. The ward is known as the climatological laboratory and was established about three years ago at the suggestion of Dr. Gunnar O. Edström. It has double walls and quadruple windows, and all visitors must pass some time in a "sluice" so as not to carry cold and humid air into the ward. The temperature is constantly at 32 C. (89.6 F.) and the relative moisture is not permitted to rise above 50 per cent, while the average figure is 35 per cent. The climate thus produced corresponds to that of Puerto Rico, although it is slightly hotter and drier. The complicated equipment required to keep the climate at a constant level has been donated by the Swedish air conditioning specialists A/B Svenska Fläktfabriken, Stockholm. The patients of Dr. Edström spend about three months in the ward. Sometimes their state improves very rapidly, but in other cases it takes weeks before any real recovery is perceptible. As there are only 2 beds in the ward, the number of patients that can be treated is necessarily small. Dr. Edström hopes, however, that in the future entire hospitals will be constructed for this treatment.

Deaths in Other Countries

Dr. Henry Briggs, for twenty-three years professor of midwifery and gynecology, University of Liverpool, and emeritus professor from 1921, died Nov. 22, 1944, at Hoylake, aged 88.

Sir Joseph Arthur Arkwright, associated with the Lister Institute since 1905 and a member of the Royal Society, died Nov. 22, 1944.—**Dr. Bernard Cuneo**, prominent surgeon, died in Paris Dec. 11, 1944, aged 71.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Dec. 23, 1944.

No Increase of Mental Breakdown Due to War

In spite of the bombing of this country from the air with considerable destruction of property and loss of life in the five years of war, there is no evidence of any increase in serious cases of mental breakdown. This summary of the effect of the war on mental health is given in the thirtieth annual report of the Board of Control, the official body which controls mental hospitals. The board points out that although admissions to mental hospitals do not by themselves give a complete picture of the incidence of psychoses and neuropsychoses they do indicate the general trend. Even in blitz areas, the report states, "there are relatively few cases in which the mental breakdown can be attributed in any degree to the effects of war" and more particularly of air raids. In those cases in which the breakdown appears to have been caused or accelerated by air raids it is generally found that the past history of the patients suggests that they might have developed mental trouble in any event, though possibly at a later date." The board mentions that a neurosis survey recently carried out by the Ministry of Health did not show any alarming increase in neuroses, particularly when allowance is made for the fact that the war has forced into industry, often in unfamiliar and trying conditions, many who previously led sheltered lives and whose breakdown under the unaccustomed strain might have been regarded as inevitable. "Looking at the situation as a whole," says the board, "we feel that it may fairly be claimed that the war has demonstrated the mental stability of the nation." At the end of 1943 the number of persons suffering from mental disorder reported under care in England and Wales was 147,557 (63,054 men and 84,503 women), a slight decrease from the year before.

Psychotherapy in Social Clubs for Patients

A remarkable new development in psychotherapy has taken place recently. It is a form of rehabilitation that is being used for patients in mental hospitals and outpatients attending psychiatric clinics. This is the institution of self-governed social clubs as part of a bigger scheme of group psychotherapy. E. B. Strauss of the department of psychologic medicine at St. Bartholomew's Hospital, Rolf Ström-Olsen of the Russell Hospital and J. Bierer of the Military Psychiatric Hospital state (*Brit. M. J.* 2:861, 1944) that the clubs have been tried for the past four years at Runwell Hospital and for two years in connection with the outpatient departments of St. Bartholomew's and Guy's hospitals and have given encouraging results. Some patients are placed in mental hospitals because they are a danger to themselves or to society. The longer they stay the less normal their lives become, it is pointed out, and this may make them worse. The social club is a successful way of breaking, or even preventing, this vicious circle. It is a successful antidote to the stigma that tells so heavily against the patient both before and after discharge from a mental hospital. It helps remove the dividing line between him and normal persons and gives him a chance to use initiative and shoulder responsibility. The number of patients who find it difficult to adapt themselves socially is overwhelming. The social club has proved to be one of the easiest ways to overcome this difficulty, the authors declare. The symptoms so far combated through the clubs are shyness and loneliness, general and social inferiority feelings, sexual maladjustment, lack of incentive and aim in life, inability to cooperate with others, anxiety and phobias, parental domination, acute disappointment and psychologic effects of physical defects.

Under war conditions the clubs meet once a week. They are run on democratic lines, a new committee being elected every three months. The chief officers are the chairman, vice chairman, secretary and organizers for games, sports, refreshments, intellectual pursuits and other activities. The officers are elected for this short term so that as many people as possible may be given responsibility. The programs consist of lectures, debates and entertainments such as games, sports, dancing lessons and dancing, whist drives, parlor games and community singing. The doctor and his assistants attend the meetings as ordinary members, but it is important that they should work behind the scenes. The social clubs are not a form of entertainment, it is emphasized, but are part of a scheme of therapy.

The United Nations Relief and Rehabilitation Administration

The European regional office of UNRRA has recruited a number of experts in public health for its work in the liberated countries of Europe and has held meetings with physicians from these countries to discuss their needs. An epidemiologic bureau has been set up, to which all countries will send information about epidemics and from which information will be distributed to all those who should be informed. An emergency unit with drugs and surgical equipment to meet the requirements of 100,000 people for one month has been formed. The unit also includes one hospital of 200 beds with an operating theater and five 40 bed hospitals. A special department will deal with displaced persons, of whom there are several millions, who want to get back to their own countries as soon as possible. UNRRA has a great responsibility with regard to the supply and distribution of food to the devastated regions. In countries in which the condition is serious they propose to have at least one nutritionist to investigate; he will have a team containing a dietitian and a biochemist.

In London Dr. Andrew Topping has assumed office as director of the health division of the European regional office. Dr. Wilbur A. Sawyer, director of health at the UNRRA headquarters in Washington, arrived in London in June to be nearer the center of operations. In London four medical officers have been appointed (two British, one French and one Dutch) in addition to two deputy directors, Dr. N. M. Goodman, British, and Dr. D. A. Reekie, American. In all the health work of UNRRA the overriding principle is to reestablish national and local health and medical services so that they can deal with their own problems at the earliest possible moment, but help will be provided in the period of transition.

Child Immigration into Australia

Australia has the same concern as European nations about her future population and has expressed a desire for more immigration, which, in any numbers, seems rather hopeless under present conditions. She has now planned child immigration. The cabinet has approved a plan to bring in an average of 17,000 children annually in age groups of 6 to 12 years for aliens and 6 to 14 for British children. Because of legal difficulties it is not proposed to plan for the introduction of child migrants by private adoption, but this will not prejudice adoption in approved cases. It is proposed to arrange with bodies such as UNRRA and the British and other governments to select suitable orphans and other children. The proposal is part of a larger immigration scheme, which the Australian high commissioner in London is discussing with the British and other governments, to bring acceptable adult immigrants from all available sources after the war. The Australian government is not in favor of the proposal to establish large groups of foreign nationals at any one place. In the sugar growing country on the north coast of Queensland, for example, there is an Italian colony which has its own schools and prints its own newspapers. This

experience has shown the undesirability of foreign settlements which do not mix with the Australian community. Australia will welcome people of all nationalities but wants them to learn English and become assimilated as quickly as possible.

The Expenditure on Nostrums

At the representative meeting of the British Medical Association Dr. J. Phillips moved a resolution which was unanimously agreed to: that the education of the public on the meretricious claims of "patent" foods, drinks and medicines should be intensified immediately. He said that \$100,000,000 a year was spent on various nostrums. Thus when government control of the use of paper has reduced the advertising pages of medical journals and at the same time greatly increased the cost of advertising space, book advertisements cease while nostrum advertisements flourish, Dr. Phillips pointed out.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, Dec. 5, 1944.

Diabetes in Brazilian Cities

Dr. Fabio C. Nunes has recently studied the incidence of diabetes in eighteen of the largest cities of Brazil, particularly Rio de Janeiro. As statistics are scarce and incomplete, Dr. Nunes's paper deals primarily with deaths from the disease. In the Brazilian cities diabetes is rated as a disease of relatively little importance in comparison with tuberculosis, with syphilis, and with the diseases of the digestive system as far as the total number of deaths is considered. Study of the mortality returns of those cities for the years 1934 to 1942 show that, for the whole nine year period, diabetes has been the cause of 0.47 per cent of all deaths, the percentage having a statistically significant increase for the three periods 1934-1936, 1937-1939 and 1940-1942: 0.36, 0.44 and 0.58 respectively. For the city of Rio de Janeiro this corresponds to 455, 623 and 656 deaths from diabetes in the three periods. For all eighteen cities, aggregating at the present time a population of 5,600,000, or about 13 per cent of the population of Brazil, these figures correspond to annual death rates of 6.6, 8.0 and 9.7 per hundred thousand of population for each of the three periods included in the study. Shown in this form, the prevalence of the disease also has a significant increasing trend, as the average annual death rate for the eighteen cities is 8.8 per hundred thousand of population for the whole period included in the study. Only the cities of Porto Alegre, São Paulo and Rio de Janeiro show, for the nine years as a whole, an average death rate from diabetes of 10 or more per hundred thousand of population (10.0, 11.2 and 13.6 respectively). For the sake of comparison it should be pointed out that the annual death rate from diabetes in the large cities of the United States is at the present time about 25 or 30 per hundred thousand of population.

For the city of Rio de Janeiro in particular, for which the statistical data are more complete, Dr. Nunes's paper shows that the deaths from diabetes for the years 1934 to 1942 represented 0.67 per cent of the total of deaths from all causes. For the years 1942 and 1943 the annual death rate was 12.0 and 12.5 per hundred thousand of population. During the last decade the annual number of deaths from diabetes has increased 45.1 per cent in Rio de Janeiro, an average annual increase of 4.5 per cent. In this city for the whole period 1932-1942, 42.5 per cent of the deaths from diabetes have been in males as against 57.5 per cent in females. But it is interesting to point out that the female percentage rises as the age increases: below 40 years female deaths from diabetes represent 40.7 per cent of the total, in the age group 40-59 years 55.5 per cent, in the age group 60-79 years 61.2 per cent and in the age group 80 years and

over 72.1 per cent. Only 8.3 per cent of all deaths from diabetes occur to those under 40, as against 41.4 per cent in the age group 40-59 and 50.3 per cent in the age group 60 years and over. The racial distribution of deaths from diabetes in Rio de Janeiro for the twelve years 1932 to 1943 has been 86.4 per cent for white people and 13.6 per cent for colored.

The Misericordia Hospital

The Misericordia Hospital of Rio de Janeiro is the oldest institution of its kind in Brazil. In 1582, eighty-two years after the discovery of Brazil by the Portuguese admiral Pedro Alvares Cabral, an armada of sixteen ships and 3,000 men, commanded by Baldez, arrived at the port after having been heavily battered for several days by stormy seas. As many members of the crews were wounded and sick, father Anchieta, the great Jesuit to whom Brazil owes so much for his pioneer work in the fields of charity and education, received the men in a large house where they found shelter and treatment. This was the beginning of a hospital that was named after Our Lady of Mercy (Nossa Senhora da Misericordia). Up to 1840 the Misericordia Hospital was a large, private infirmary, old, dark and in part underground. Since then it has been remodeled and enlarged several times, the newest improvements having been completed last year.

The present institution is a private hospital, largely for free patients, which consists of thirty-one wards, with more than 900 beds, and 43 outpatient clinics for all the medical and surgical specialties of present practice. During the year 1943, 8,512 patients were interned in the wards of the Misericordia Hospital, and a total of 123,754 individual visits were registered at the outpatient clinics, where 55,022 dressings were done, 88,625 injections were applied and 1,631 minor operations were performed. For the wards and the clinics the pharmacy furnished 281,308 prescriptions. A great improvement, started two years ago, was the creation of a laboratory for the preparation of parenteral products; the laboratory manufactured 441,776 ampules during the year 1943, resulting in a great saving of money to the institution. The Institute of Physical Therapy is now operating powerful equipment for high voltage roentgen therapy and is using about 50 cg. of radium. One important new feature of the hospital is its center of postgraduate teaching, which has just begun another course on the subject of arterial hypertension under the direction of Dr. Genival Londres, professor of medicine at the Rio de Janeiro School of Medical Sciences. The superintendent of the Misericordia Hospital is Dr. Ary A. Silva and the medical director is Dr. Paulo Cesar de Andrade.

Marriages

LUCIANO E. DE MARCO, Newark, N. J., to Miss Clare Magdalene Enzbrenner of Altoona, Pa., in South Orange, N. J., November 5.

GEORGE A. MICHELSON, San Francisco, to Miss Helen L. Ashford of Charlotte, N. C., at York, S. C., November 11.

JOHN WARREN MANNING 3d, Philadelphia, to Miss Muriel Elizabeth Johnson at Lakewood, N. J., October 15.

KEVIN MICHAEL COSGROVE, St. Johnsbury, Vt., to Miss Joan McGrath of Bronxville, N. Y., December 9.

NICHOLAS AYLWARD KNOX, Woodhaven, N. Y., to Miss Irene Vaughan in Brooklyn, October 21.

CORNELIUS E. GORMAN, Lynchburg, Va., to Miss Elizabeth Skender of Canton, Ill., October 17.

TOM R. ROBERTS, Crowell, Texas, to Miss Laura Mae Hunter in Dallas, November 4.

THOMAS J. NAUGHTON to Miss Elizabeth Roughan McMahon, both of Chicago, November 27.

CHARLES A. BECK to Miss Ruth Brandstetter, both of Chicago, December 10.

Deaths

Lloyd Hiram Ziegler • Wauwatosa, Wis.; University of Minnesota Medical School, Minneapolis, 1921; assistant in psychology at Indiana University from 1914 to 1917; an intern at St. Elizabeths Hospital, Washington, D. C., for the year 1920-1921, when he also was assistant in clinical psychiatry at George Washington University; an officer in the United States Public Health Service Reserve from 1921 to 1923; reconstruction officer and assistant clinical director, Government Hospital number 37, Waukesha, Wis., and assistant in psychiatry at the Henry Phipps Psychiatric Clinic, Johns Hopkins Hospital, Baltimore, in 1923 and 1924; a fellow in medicine at the Mayo Foundation for the year ended in 1925, when he left to become associate professor in neuropsychiatry at the University of Colorado School of Medicine, Denver, and resident psychiatrist at the Colorado Psychopathic Hospital; became an associate in neurology at the Mayo Clinic in May 1926 and instructor in neurology at the Mayo Foundation, Aug. 17, 1928; became professor of neurology and psychiatry at the Albany Medical College and neurologist and psychiatrist in chief for the Albany Hospital, Albany, N. Y., in 1930; a founder member and member of the board of directors of the American Board of Psychiatry and Neurology, Inc.; member of the American Neurological Association, American Psychiatric Association, Association for Research in Nervous and Mental Diseases, Minnesota Society of Neurology and Psychiatry, Albany County Mental Hygiene Association, New York Psychiatric Society, the Alumni Association of the Mayo Foundation, American Association for the Advancement of Science and the Central Neuropsychiatric Association; in 1931 attended the first International Neurological Congress in Berne, Switzerland, and in 1935 the second congress, which convened in London; lecturer in psychiatry at the University of Illinois College of Medicine, Chicago; in November 1937 became associate director and in April 1942 medical director of the Milwaukee Sanitarium, Wauwatosa; instrumental in organizing the Veterans' rehabilitation clinic in Milwaukee; collapsed and died on the grounds of the Milwaukee Sanitarium January 8, aged 52, of a coronary attack.

William Francis Wild • Jackson Heights, N. Y.; Medical Department of Tulane University of Louisiana, New Orleans, 1906; district health officer, department of health, Williamsburg-Greenpoint Health Center; life member of the American Public Health Association; served as president of the Connecticut Public Health Association and as executive secretary of the Minnesota Public Health Association; at one time served with the American Society for the Control of Cancer and the American Child Health Association; formerly health officer of Bridgeport, Conn., the city of Norfolk, Va., and the counties of Nansemond and Isle of Wight; formerly associated with the Nebraska State Board of Health in Lincoln; died in the Beth Moses Hospital, Brooklyn, November 13, aged 62, of pneumococcal meningitis.

Frank Leander Morse, Somerville, Mass.; Harvard Medical School, Boston, 1894; member of the American Medical Association; medical and sanitary inspector of the Massachusetts Board of Health from 1898 to 1905 and a district health officer from 1909 to 1915; from 1901 until his retirement in 1942 medical inspector for the Somerville Board of Health; formerly in charge of the Somerville Contagious Disease Hospital; discharged from active service in the U. S. Army in 1919 with the rank of lieutenant colonel and was retired from the Officers Reserve Corps in 1935 with the rank of colonel; served on the staffs of the Boston City Hospital and the Somerville Hospital, where he died November 5, aged 73, of carcinoma of the prostate.

Archie Clifford Van Cleve • Portland, Ore.; University of Oregon Medical School, Portland, 1913; also a pharmacist; served during World War I; colonel, medical reserve corps, U. S. Army, not on active duty; formerly member of the state board of health; division surgeon of Associated Oil Company and Texas Oil Company; chief surgeon of Portland Gas and Coke Company; surgeon for Postal Telegraph Company and Mackay Radio; served for eleven years as assistant surgeon to the Union Pacific Railroad Company; for ten years member of the boxing commission of Portland; interned at and member of the staff of St. Vincent's Hospital; on the staff of the Providence Hospital; died November 10, aged 59, of coronary sclerosis.

Thomas Maze Aderhold • El Reno, Okla.; Northwestern University Medical School, Chicago, 1901; an Affiliate Fellow of the American Medical Association; fellow of the American College of Surgeons; served for eighteen months as an Ameri-

can Red Cross doctor in the Boer War in South Africa; at one time surgeon at the Zeigler Hospital, Zeigler, Ill.; for many years surgeon and formerly owner of the El Reno Sanitarium; charter member and past president of the El Reno Lions Club and past president of the chamber of commerce; died in a Dallas hospital September 6, aged 72, of myocarditis and arteriosclerosis.

Clyde Lipsey McNeil • Rogers, Ark.; Vanderbilt University School of Medicine, Nashville, Tenn., 1917; fellow of the American College of Surgeons; councilor of the Tenth District of the Arkansas Medical Society; interned at the Vassar Brothers Hospital in Poughkeepsie, N. Y.; served in the medical corps of the U. S. Army during World War I; a member of the board of directors of the chamber of commerce and of the First Federal Savings and Loan Association; a charter member and past president of the Rogers Kiwanis Club; died November 24, aged 52.

Hughes Dayton • Irvington, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1898; formerly instructor in physical diagnosis at the Cornell University Medical College, New York, and associate attending physician at the New York Hospital and the Hudson River State Hospital, New York; on the staff as consulting physician at the Grasslands Hospital, Valhalla, United Hospital, Port Chester, and the Tarrytown Hospital, Tarrytown, where he died December 3, aged 71, of cerebral hemorrhage due to hypertensive cardiovascular disease.

Ignatz Leo Nascher, Staten Island, N. Y.; University of the City of New York Medical Department, New York, 1885; for nearly twenty years served with the Departments of Public Welfare and Hospitals in the City of New York, serving as chief physician of the latter; formerly special lecturer on geriatrics, Fordham University School of Medicine, and chief of clinic department of internal medicine, Mount Sinai Hospital Dispensary, New York; author of "Geriatrics, the Diseases of Old Age and Their Treatment"; died December 25, aged 81, of anginal syndrome.

Robert Martin Akers, Kermit, W. Va.; Lincoln Memorial University Medical Department, Knoxville, Tenn., 1910; twice elected mayor of Kermit; surgeon for the Norfolk and Western Railway for many years; died in Huntington, W. Va., November 24, aged 60, of myocarditis.

Fred Delmar Andrew, Rochester, N. Y.; College of Physicians and Surgeons, New York, 1887; specialist certified by the American Board of Radiology, Inc.; member of the American Medical Association and the American College of Radiology; roentgenologist at the Monroe County Hospital; honorary staff member, Strong Memorial Hospital, where he died December 11, aged 88, of pneumonia.

Scott Carter Applewhite • San Antonio, Texas; Jefferson Medical College of Philadelphia, 1901; on the staffs of the Santa Rosa, Nix, Medical Arts and Medical and Surgical Memorial hospitals; served during World War I; died November 17, aged 68, of acute arteriosclerosis.

Edward S. Beck, Owego, N. Y.; University of Buffalo School of Medicine, 1888; member of the American Medical Association; formerly a pharmacist; past president of the Tioga County Medical Society; served as county coroner for many years; died in the Robert Packer Hospital, Sayre, Pa., November 13, aged 82, of chronic myocarditis (arteriosclerotic).

Alvin Marion Belcher, Auburn, Ky.; University of Tennessee Medical Department, Nashville, 1900; Hospital College of Medicine, Louisville, 1901; died November 19, aged 71, of injuries received in an automobile accident.

Frank Moxon Beresford, Ardmore, Pa.; Marquette University School of Medicine, Milwaukee, 1919; specialist certified by the American Board of Otolaryngology; formerly medical director of the Provident Mutual Life Insurance Company, Philadelphia; served during World War I; at one time lieutenant in the medical corps, U. S. Navy; member of the American Medical Association; died in Spring City October 25, aged 54, of coronary thrombosis.

George W. Booker, Knoxville, Tenn.; Tennessee Medical College, 1901; member of the American Medical Association; for two terms Knox County physician; died November 17, aged 82, of atrophy of the heart muscle.

John R. Brian, St. Francisville, Ill.; Barnes Medical College, St. Louis, 1899; died November 18, aged 74, of coronary thrombosis.

William D. H. Brown, La Grange, Ill.; National Medical University, Chicago, 1902; died in Chicago December 6, aged 86, of multiple lacerations of the right lung with massive hemothorax due to multiple fracture of the ribs as the result of a fall from a porch.

Robert Miller Campbell, Glendale, Calif.; Medical College of Indiana, Indianapolis, 1903; formerly postmaster in La Fayette, Ind., health officer of Tippecanoe County, Ind., and for many years on the board of the Tippecanoe County Tuberculosis Association; died November 11, aged 74, of cerebral hemorrhage.

Charles W. Case, Onsted, Mich.; Medico-Chirurgical College of Philadelphia, 1899; member of the American Medical Association; on the staff of the Bixby Hospital, Adrian; died November 11, aged 65, of carcinoma of the liver.

Walter Chrystie ♂ Bryn Mawr, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1883; served on the staff of the Bryn Mawr Hospital, where he died October 9, aged 83, of injuries received when struck by an automobile.

Henry Clay Clements, Benton, Ala.; Medical College of Alabama, Mobile, 1899; member of the American Medical Association; died in a Selma hospital October 30, aged 67, of congestive heart disease and chronic myocarditis.

Louis T. Donaldson, Jennings, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1907; member of the American Medical Association; director of the Jefferson Davis Health Unit; died in the Southern Baptist Hospital, New Orleans, November 4, aged 60, of coronary occlusion.

Robert Morris Dunsmoor, Fontana, Calif.; College of Physicians and Surgeons, Los Angeles, 1913; died November 7, aged 61, of arteriosclerosis.

Louis M. Dusseldorf, Brooklyn; Long Island College Hospital, Brooklyn, 1888; member of the American Medical Association; on the courtesy staff of the Methodist Hospital, where he died November 11, aged 78, of bronchopneumonia, cerebral thrombosis and hypertension.

John Robert Eby, Elko, Nev.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1893; past president of the Elko County Medical Society; at one time chief of staff, Elko General Hospital, where he died October 27, aged 76, of myocardial infarction.

John Wesley Edwards, Staten Island, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; a captain in the medical corps of the U. S. Army during World War I; for many years an acting assistant surgeon in the U. S. Public Health Service on duty at the U. S. Quarantine Station in Boston; retired in 1936; died September 25, aged 76, of generalized arteriosclerosis.

Charles Wager Fairchild ♂ New York; Columbia University College of Physicians and Surgeons, New York, 1903; on the courtesy staff of the Tarrytown Hospital, Tarrytown; on the staff of the Manhattan State Hospital; died in St. Vincent's Hospital November 15, aged 65, of hypertensive cardiovascular disease.

John David Fakes, Hickman, Ky.; Barnes Medical College, St. Louis, 1899; Hospital College of Medicine, Louisville, Ky., 1900; died in the Keys-Houston Clinic Hospital, Murray, November 11, aged 75, of cirrhosis of the liver.

Thomas Enoch Ferrell, Mountain View, Mo.; Barnes Medical College, St. Louis, 1895; member of the American Medical Association; died in St. John's Hospital, Springfield, November 13, aged 74, of coronary occlusion.

Hamilton S. Gillespie, Sioux City, Iowa; Omaha (Neb.) Medical College, 1898; member of the American Medical Association; past president of the Woodbury County Medical Society; died in St. Joseph Hospital November 14, aged 69, of coronary thrombosis.

James Frank Gullette, Austin, Texas; Memphis (Tenn.) Medical College, 1904; died in an Austin hospital September 24, aged 65, of coronary thrombosis.

C. I. Harris, Morganfield, Ky.; Hospital College of Medicine, Louisville, 1904; past president of the Union County Medical Society; on the staff of the Union County Hospital; died November 17, aged 68, of heart disease.

Daniel Webster Henry, Endicott, Wash.; Jefferson Medical College of Philadelphia, 1905; member of the American Medical Association; died November 10, aged 65, of coronary thrombosis.

William E. Hervey, West Alexander, Pa.; Medical College of Ohio, Cincinnati, 1882; at one time president of the chamber of commerce in Pittsburgh; died in the Ohio Valley General Hospital, Wheeling, W. Va., November 6, aged 89, of fracture of the neck of the femur and senility.

Jacob Oliver Hoffman, Harrisonburg, Va.; University of Michigan Homeopathic Medical School, Ann Arbor, 1883; died September 4, aged 84, of acute prostatitis.

Brooke Ignatius Jamison, Emmitsburg, Md.; University of Maryland School of Medicine, Baltimore, 1905; died November 8, aged 62, of injuries received when struck by an automobile.

James Keho, Tacoma, Wash.; State University of Iowa College of Medicine, Iowa City, 1884; died November 3, aged 86, of cerebral hemorrhage.

Otto Kiene ♂ Concordia, Kan.; Kansas Medical College Medical Department of Washburn College, Topeka, 1904; died in a Kansas City hospital November 6, aged 66, of pulmonary infarct.

Patrick Joseph Kingsley, Milton, Mass. (licensed in Massachusetts in 1899); aged 74, died September 25, of hemorrhage due to gastric ulcer.

George William Kittelberger ♂ Bowie, Texas; St. Louis University School of Medicine, 1932; member of the Missouri State Medical Association; served an internship at the Bethesda Hospital in St. Louis, St. Luke's Hospital and Shriners' Hospital for Crippled Children in Spokane, Wash.; formerly on the staff of the Eastern State Custodial School in Medical Lake, Wash.; died November 1, aged 44, of brain tumor.

James Henry Lacey, Denver; St. Louis Medical College, 1883; Jefferson Medical College of Philadelphia, 1893; for many years surgeon for the Southern Railway; died in the Denver General Hospital October 31, aged 87, of hypostatic pneumonia, following a fracture of the right femur received in a fall.

Jonathan Morias Larson, Hollywood, Fla.; National Medical University, Chicago, 1905; died November 6, aged 71, of postoperative shock following a cholecystectomy.

Florance Patrick Leehey, Oelwein, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; member of the American Medical Association; for fifteen years city physician; served during World War I; head of the Selective Service Board; on the staff of the Mercy Hospital; died November 6, aged 69, of heart disease.

Charles Robert Lewis ♂ Akron, Ohio; Ohio State University College of Medicine, Columbus, 1916; on the staffs of the City Hospital, St. Thomas Hospital and the Peoples Hospital, where he died November 6, aged 62, of pneumonia.

Robert Kirkpatrick Macklin, Pasadena, Calif.; Northwestern University Medical School, Chicago, 1911; served in the medical corps of the U. S. Army during World War I; died November 15, aged 59, of intracranial pressure.

Ira Newton Martin, Portsmouth, Ohio; Eclectic Medical Institute, Cincinnati, 1906; past president of the Hempstead Academy of Medicine; died October 23, aged 72, of cerebral hemorrhage.

Sidney Simon Mayer Jr., Portland, Ore.; University of Oregon Medical School, Portland, 1936; member of the American Medical Association; clinical associate in medicine at his alma mater; served an internship and residency at Johns Hopkins Hospital, Baltimore; died November 2, aged 33, following a thyroidectomy.

Martin McAulay ♂ Monterey, Calif.; Hahnemann Medical College of the Pacific, San Francisco, 1904; past president of the Monterey County Medical Society; served during World War I; formerly physician and owner of the El Adobe Hospital; served on the staffs of the Peninsula Community Hospital, Carmel, and the Monterey Hospital; died November 3, aged 69, of carcinoma of the mouth.

Joseph Fennell McKee ♂ Chicago; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1894; on the staffs of Anne's Hospital and the Lutheran Deaconess Hospital, where he died September 28, aged 76, of uremia.

Elmer L. Mullin, Manlius, Ill.; Illinois Medical College, Chicago, 1905; on the staff of the Julia Rackley Perry Memorial Hospital, Princeton; died in the Presbyterian Hospital, Chicago, November 12, aged 69, of carcinoma of the bladder.

William S. Napper, Lebanon Junction, Ky.; University of Louisville Medical Department, 1891; died October 26, aged 84, of chronic nephritis.

John Francis Nooe ♂ Boerne, Texas; University of Texas School of Medicine, Galveston, 1898; served as a captain in the medical corps of the U. S. Army during World War I; died in San Antonio October 30, aged 71, of coronary thrombosis.

Oscar C. Pabst, Tyler, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1895; member of the American Medical Association; died suddenly October 14, aged 78, of coronary thrombosis.

Benjamin Hamilton Parrish, Cloverport, Ky.; University of Louisville School of Medicine, Louisville, 1913; member of the American Medical Association; died October 13, aged 58, of cerebral hemorrhage.

George F. Plotner, West Mansfield, Ohio; Starling Medical College, Columbus, 1888; died in Cincinnati November 4, aged 85, of cardiovascular renal disease.

Nathan Sylvester Rawdin © New York; Baltimore University School of Medicine, 1900; died October 31, aged 69, of coronary thrombosis.

John King Rector, Washington, D. C.; Howard University College of Medicine, Washington, 1921; served as assistant medical director of the Freedmen's Hospital; died in the Glenn Dale Sanatorium, Glenn Dale, Md., November 9, aged 49, of pulmonary tuberculosis.

Guy Cyrus Rich, Los Angeles; Jefferson Medical College of Philadelphia, 1885; also a dentist; formerly practiced medicine in Sioux City, Iowa; died October 22, aged 83, of carcinoma of the throat.

Edward Karl Richard, Olean, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1918; member of the American Medical Association; served as instructor in medicine at the University of Rochester School of Medicine and Dentistry; formerly on the staffs of the Genesee and Strong Memorial hospitals, Rochester; served as medical superintendent of the Rocky Crest Sanatorium; on the staffs of the Olean General and St. Francis hospitals and the Mountain Clinic; died November 15, aged 51, of coronary occlusion.

John N. Rock © Milwaukee; Rush Medical College, Chicago, 1891; died November 26, aged 79, of coronary arteriosclerosis.

Clarence A. Rogers, Bluefield, W. Va.; Leonard Medical School, Raleigh, N. C., 1912; owner of the Providence Hospital; died November 22, aged 59, of cerebral hemorrhage.

Paul Corcoran Ryan © Pittsburgh; University of Michigan Medical School, Ann Arbor, 1936; served an internship at the Harper Hospital in Detroit and a residency in ophthalmology at the University Hospitals in Iowa City; member of the staffs of St. John's, Shadyside and the Eye, Ear, Nose and Throat hospitals; died November 13, aged 37, of rheumatic heart disease and mitral stenosis.

Henry Fenno Sawtelle © Arroyo Grande, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; U. S. Army Medical School, 1926; served during World War I; formerly a major in the medical corps of the U. S. Army; at one time medical examiner for the pension office in Washington, D. C., where he later became chief sanitary inspector for the health department and assistant health officer; died December 2, aged 66.

Clarke Wesley Shepherd, Spring Hill, W. Va.; Baltimore University School of Medicine, 1891; died in the Memorial Hospital, Huntington, December 18, aged 80, of uremia, myocardial failure and pulmonary edema.

Kathryn Forbich Thumm Smith, Casper, Wyo.; Jenner Medical College, Chicago, 1914; member of the American Medical Association; died in Cheyenne November 29, aged 71, of uremia.

Philip McClellan Steckman © Plattsburg, Mo.; Jefferson Medical College of Philadelphia, 1889; died in a hospital in St. Joseph November 11, aged 79, of esophageal hemorrhage.

Glenn Morris Steele, Tacoma, Wash.; the Hahnemann Medical College and Hospital, Chicago, 1903; member of the American Medical Association; died December 3, aged 66, of carcinoma of the stomach.

Lawrence Henry Stepp, Mars, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1895; member of the American Medical Association; past president of the board of health and Kiwanis Club of Mars; died November 26, aged 77, of angina pectoris.

Archibald William Thompson © Buffalo; University of Buffalo School of Medicine, 1916; member of the Radiological Society of North America, Inc.; specialist certified by the American Board of Radiology, Inc.; served during World War I; on the staffs of the Lafayette General and Our Lady of Victory hospitals; died in Eden, N. Y., October 22, aged 53, of carcinoma.

Francis Elmer Wilhelm © Kansas City, Kan.; University of Kansas School of Medicine, 1906; an Affiliate Fellow of the American Medical Association; member of the Missouri State Medical Association; served on the staffs of St. Luke's and St. Joseph hospitals, Kansas City, Mo.; died September 26, aged 71, of rheumatic heart disease and probably heart block.

DIED WHILE IN MILITARY SERVICE

Raymond Leo Abraham, Chicago; Loyola University School of Medicine, Chicago, 1933; member of the American Medical Association; served an internship at St. Elizabeth Hospital; commissioned a first lieutenant in the medical corps, Army of the United States, on June 3, 1942; later promoted to captain; died at the Charleston port of embarkation, South Carolina, Sept. 27, 1944, aged 38, of coronary thrombosis.

William Etheridge Dierking, Passed Assistant Surgeon, Lieutenant, U. S. Navy, Louisville, Ky.; University School of Louisville School of Medicine, 1939; member of the American Medical Association; served an internship at St. Elizabeth Hospital, Covington, and a residency in pediatrics at the Louisville City Hospital; commissioned a lieutenant (jg), medical corps, U. S. Navy, on April 14, 1942; promoted to lieutenant on Oct. 1, 1942; died Aug. 31, 1944, aged 31, of acute poisoning, substance unknown.

Richard Franklin Halford, Augusta, Ga.; University of Georgia School of Medicine, Augusta, 1940; served an internship at the James M. Jackson Memorial Hospital, Miami, Fla.; commissioned a first lieutenant in the medical corps of the Army of the United States on Aug. 7, 1941; later promoted to captain; flight surgeon during the first invasion of North Africa and on other battle fronts; died in the North African theater of operation August 17, 1944, aged 28, in an airplane crash.

Robert McCurdy Kennedy, Elgin, Ill.; Northwestern University Medical School, Chicago, 1938; diplomate of the National Board of Medical Examiners; served an internship at City of Detroit Receiving Hospital, Detroit; formerly a medical missionary to India; commissioned a lieutenant (jg) in the medical corps, U. S. Naval Reserve, on Oct. 27, 1943; drowned at sea when the ship sank in a hurricane in the Atlantic area Sept. 13, 1944, aged 33.

Gayle Harold Laymon, St. Joseph, Ill.; Chicago Medical School, 1934; member of the American Medical Association; served an internship at the South Shore Hospital, Chicago; commissioned a first lieutenant in the medical corps, Army of the United States, on Dec. 28, 1942; began active duty on Jan. 13, 1943; later promoted to captain; died in Kodiak, Alaska, April 9, 1944, aged 42, as the result of cerebrovascular disease.

Thomas Joseph Lennon © San Francisco; University of California Medical School, San Francisco, 1924; formerly an intern at the San Francisco Hospital; at one time resident physician at St. Mary's Hospital, where he was chief of medicine and member of the executive committee; served as clinical instructor in medicine at his alma mater; commissioned a captain in the medical corps, Army of the United States, on Jan. 15, 1941; began active duty on May 15, 1942; promoted to major; served overseas with the 30th General Hospital; died in the Hammond General Hospital, Modesto, Nov. 13, 1944, aged 48, of carcinoma of the lung.

John Anthony Mastromarino, Revere, Mass.; Middlesex University School of Medicine, Waltham, 1940; served an internship at St. Luke's Hospital in Newburgh, N. Y., and a residency at the Cornwall Hospital, Cornwall, N. Y.; commissioned a first lieutenant in the medical corps, Army of the United States, on May 17, 1943; died in the Southwest Pacific area Oct. 26, 1944, aged 29, of yellow atrophy of the liver.

Wesley Nestor Warvi, Lead, S. D.; University of Wisconsin Medical School, Madison, 1939; served an internship at the University of Kansas Hospitals, Kansas City, Kan., and a residency at the Collis P. Huntington Memorial Hospital in Boston and the Cincinnati General Hospital in Cincinnati; commissioned a first lieutenant in the medical corps, Army of the United States, on Dec. 30, 1943; killed in an automobile accident near Ogallala, Neb., July 30, 1944, aged 34.

Jonathan Wooden Williamson, Atlanta, Ga.; Emory University School of Medicine, Atlanta, 1939; associate member of the Medical Association of Georgia; served an internship at the Grady Hospital; commissioned a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on July 25, 1941; later commissioned a lieutenant; died April 27, 1943, aged 28.

Correspondence

APPRAISAL OF NEW DRUGS

To the Editor:—Introduction of new chemical agents for clinical use involves a serious responsibility and requires the utmost care in skilful execution and interpretation of laboratory findings and sound judgment in evaluation of clinical results, as emphasized years ago (*THE JOURNAL*, Nov. 23, 1929, p. 1632). Both laboratory and clinical studies must conform to the best accepted standards for the specific types of experiments involved. The desirability of setting up a universally standard scheme of appraisal, such as that authorized "as a pattern" by the Council on Pharmacy and Chemistry in *THE JOURNAL*, Dec. 9, 1944, page 958, may nevertheless be questioned. Aside from differences of opinion regarding the most valid technics for particular phases of a standardized appraisal, it is doubted that standardization of the experimental background for new drugs should be as detailed as that recommended.

Ultimately the value of any chemical agent in treatment depends on the relation between its therapeutic hazard and the disease hazard. Neither of these factors can be satisfactorily quantified. The therapeutic hazard may be established only roughly from laboratory studies or even preliminary clinical trials and may be changed appreciably by variations in the disease process. The disease hazard often varies during the course of the process and also with many factors whose evaluation involves the art of medicine rather than judgment based on quantitative data. Final evaluation of new drugs always depends on the trained senses of many experienced clinicians after release of the agent for general use, and only indirectly on the preliminary clinical tests and laboratory findings. The problems involved in the introduction of new drugs then resolve themselves into (a) recognition of appreciable therapeutic efficacy and (b) recognition of toxic effects. Assuming reasonably favorable laboratory reports of efficacy, the significant data in this regard must come from the preliminary clinical trials. On the other hand, the toxic hazards should be so well understood from laboratory studies that no human material is sacrificed in preliminary clinical experiments.

Laboratory experiments should therefore be directed not toward extensive pharmacodynamic tests with toxicity tests secondary but toward exhaustive study of toxic hazards with integration of the information so gained into the pharmacodynamic matrix. The proposed standardized appraisal does not stress the necessity of using toward this end the multitudinous phases of study recommended. For example, it is as important to study the toxic hazard in disease states as it is to determine the efficacy of the drug in these conditions, and the pharmacodynamic knowledge would not suffer by inclusion of studies with a drug level in the toxic range. Studies of absorption, distribution and fate of new agents also should be carried out with toxic as well as therapeutic doses.

The proposed evaluation of toxicity in the standardized appraisal could well be more flexible. More useful information can be obtained, for example, by a relatively casual study of effects of central nervous system drugs on a single species among the primates or other large mammals than by any amount of work on batrachians or small rodents. Enough species should certainly be included to yield a clear picture of the degree of species variability, but the species chosen and their number should be selected intelligently to match the properties of the drug. Thorough study of a few appropriate species is preferable to an extensive, less accurate study.

The use of a therapeutic index defined as ED_{50}/LD_{50} is of value only in rough comparison of compounds in the earlier stages of laboratory development. Abuse of this ratio to denote relative safety of compounds used clinically is not unknown. The clinician is interested primarily in the margin of safety,

which can also be expressed in the form of a ratio as the certain safety factor (LD_{50}/ED_{50}).

Especially for drugs likely to be used repeatedly, estimations of subacute and chronic toxicities are essential. However, insistence on studying effects for the entire life span of "at least one species" seems pointless; we are not aware of any drug for which additional information regarding any factor except life span itself could be obtained with this technic which could not be obtained equally well from properly designed experiments covering a shorter period, such as six to nine months for mice. Estimations of acute or subacute toxicity in very young and senile animals may be necessary for certain drug types, but the indirect gathering of this information by conforming to a standardized appraisal recommending treatment throughout the life span can but result in delay in introduction of possibly useful agents.

Criticism of a standard appraisal scheme suitable for all types of drugs should not be construed as a criticism of standardization of study of specific types. The proposed detailed plan is stated to be applicable to evaluation of "really new drugs," and short cuts in the procedures are condoned for "a few isolated cases" only. Most new agents introduced recently, such as the barbiturates, phenalkylamines and antispasmodics, have been designed as modifications of recognized useful agents. Comparative studies of efficacy and toxic hazards of these should be intensive in those phases indicated by past experience with the type compounds. In each group of compounds, however, only a fraction of the procedures noted in the standard appraisal need be carried out. For studies of this kind, general agreement as to the validity of the appropriate methods of study would be helpful.

Basically there is no moral difference between deaths caused by the useless withholding of new superior agents and deaths caused by premature use of untested agents. Any aids to evaluation of new compounds must recognize this, and we do not believe that the aim of fostering therapeutic research for the betterment of pharmacotherapy is served well by overly critical standards for preliminary study of new agents.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Medical and Surgical Treatment in Bronchiectasis.—

According to Alexander the safety of pulmonary lobectomy has solved the problem of treatment for approximately half the bronchiectasis patients; the other half, for various reasons (especially because of extensive bilateral lesions), are not suitable for the operation. Nonsurgical methods of treatment, if properly and faithfully carried out, can be made effective in greatly alleviating the distressing symptoms of the disease in a large majority of patients in spite of the pessimistic opinions about the value of nonsurgical treatment that have been expressed recently.

Sternal Puncture as Diagnostic Procedure.—Propp and Schwind studied 140 cases of diseases of the blood and hemopoietic system and cases in which the possibility of such disorders entered into the differential diagnosis. Twenty punctures on patients without hematologic disorders and ranging in age from 17 to 41 years served as normal standards. Sternal puncture is an extremely valuable and practical diagnostic method. Elaborate techniques of handling and studying the marrow samples, however valuable from a research standpoint, are unnecessary for clinical use. Indicated punctures gave information of clinical value in 65 per cent of the cases. Diagnosis was established by puncture in 16.2 per cent of the 74 indicated cases. Sternal puncture cannot be substituted for thorough clinical investigation. The more thorough the work-up of the patient, the easier and more valuable is the interpretation of the puncture. Most diseases do not show specific changes in the marrow from which a definite diagnosis can be made, but much valuable information can be obtained which is of aid in the differential diagnosis and subsequent handling of the patient. Diagnoses should be made only from specific myelograms. A negative result does not absolutely preclude the presence of a given disease because of the possibility of not having secured a representative sample of marrow and of atypical variations in the pathologic lesions of the disease. Punctures which yield no marrow cells on aspiration should be followed by a trephine biopsy, if the diagnosis can be reached in no other way and no contraindication is present.

Kala Azar in China.—Kala azar is endemic throughout the whole of China north of the Yangtze River. It is most common below the age of 15, although in the series of 585 cases reported by Scovel there was an unusually large number of patients from 15 to 40 years of age. Most of the patients are from the farmer or coolie class living in small villages. Epidemiologic studies point to the sandfly as the vector and the dog as the reservoir host for the parasites. This is borne out by the ability of *Phlebotomus chinensis* to receive and retain

the parasites even in the absence of blood, by the growth of flagellates in the intestine of the fly and their forward extension into the proboscis, by the apparent identical nature of *Leishmania canis* and *donovani* as revealed by similar complement fixation reactions and by direct transmission of the disease to man through the bite of infected flies. The most important physical signs are an enlarged spleen, a low grade fever with tachycardia, anemia, most pronounced in children, and a leukopenia, which is more severe in the older and more chronic cases. Sternal marrow smears were positive in 81 per cent of 557 examinations and constituted the most valuable means of diagnosis. Complications were more frequent in older patients with a protracted history. The most common of these were pneumonia, amebic and bacillary dysentery, bronchitis and noma. There were thirty deaths in 585 patients, a mortality rate of 5.1 per cent. Only 3 of these succumbed to kala azar alone, the remaining having complications, mostly pneumonia. Six relapses occurred. Prophylaxis should consist in eradication of sandfly breeding places, removal of infected dogs and segregation of patients. Untreated patients gradually lose weight and strength until their debilitated condition makes them subject to some complication, which is usually the cause of death. Kala azar responds readily to treatment with antimony. The author used pentavalent antimony compounds (neostibosan and neostam), giving approximately 1 Gm. to 33 pounds (15 Kg.) of body weight in nine to sixteen intravenous injections of a 0.5 per cent solution. Few reactions occurred with neostibosan. Gastrointestinal upsets were common in patients receiving neostam (stibamine glucoside). The parasites disappear more slowly from the bone marrow than from the liver and spleen. Antimony is contraindicated in the presence of jaundice, hepatitis, pneumonia or acute nephritis.

- Arteriosclerosis. W. C. Hueper.—p. 245.

Pathologic Anatomy of 'Atypical Pneumonia.—During the years 1940 to 1944 the central pathologic laboratory of the United States Army collected 90 cases of "atypical pneumonia, etiology undetermined," in which postmortem examinations were made. Golden analyzes the morbid anatomic changes in the 42 cases of that series in which case histories and necropsy protocols are reasonably complete and enough tissue was available for an unequivocal estimate of the pathologic process. All of the cases acceptable for this report were cases of acute interstitial pneumonitis, a designation which the author uses in preference to the clinical designation of "atypical pneumonia, etiology undetermined." In a number of instances portions of the lungs at necropsy showed bronchopneumonia and occasionally lobar pneumonia, as well as areas of acute interstitial pneumonitis. The composite description is based on 21 cases in which multiple sections of lung revealed only acute interstitial pneumonitis. The following were the pathologic changes displayed by all cases in common: 1. There was acute bronchiolitis, focally distributed, in which desquamation of the mucosal surfaces occurred early. 2. The lumens of such bronchioles contained pus, mucoid fluid and desquamated epithelial clusters or single cells, sometimes in an advanced stage of disintegration. 3. Bacteria in small numbers and not of uniform type could be demonstrated in the bronchiolar pus in some cases. 4. The bronchioles were dilated, even in cases in which death occurred early in the disease. 5. The walls of such bronchioles were infiltrated chiefly with mononuclear cells, which extended radially into the regional interstitial tissues of the lung, namely the peribronchiolar tissues, the alveolar walls and the pulmonary septums. 6. The alveoli either contained air or were collapsed, and they differed from those involved in bronchopneumonia and lobar pneumonia in being relatively free of polymorphonuclear leuko-

cytic exudate. 7. Such areas failed to reveal micro-organisms on tissue section. 8. With the advent of secondary bacterial invasion the gross and microscopic pictures were altered: in some cases it was possible to discover areas of acute interstitial pneumonitis adjacent to zones of typical bronchopneumonia, lobar pneumonia or pulmonary abscess. The chief lesions were comparable to those of certain other infections, notably of influenza pneumonia uncomplicated by secondary bacterial infection and of uncomplicated measles pneumonia. There is anatomic evidence indicating that these lesions are caused by one or more viruses.

Topical Applications in Healing of Wounds.—Williams and Bissell studied the effects of vitamins and various other substances on the acceleration of healing when applied topically to wounds of uniform size in normal rats. The substances studied were vitamins A, C, D and E, thiamine hydrochloride, nicotinic acid, riboflavin, calcium pantothenate, pyridoxine, biotin, hydrosulphosol, bitydine, urea-sulfathiazole ointment, amino acids, adenosine, liver extract, cod liver oil, a "vitamin mixture" and sesame oil. The effect of sulfamerazine used in conjunction with most of these substances was also observed. No definite benefit was derived from the use of any of these substances as judged by frequent observations of the wounds and the microscopic changes.

Penicillin in Chronic Osteomyelitis.—Anderson and his associates report 40 cases of chronic osteomyelitis treated with penicillin. In 25 it has been possible to conduct follow-up observations for a year or longer after completion of the first course of treatment with penicillin. Most of the patients had received intensive therapy with sulfonamide drugs without benefit, and many of them had had recent surgical treatment. *Staphylococcus aureus* was cultured from material from the local lesion in all but 2 cases. In 31 of the 40 cases only one course of penicillin therapy was given, while in 9 penicillin was given on two separate occasions. All the patients received penicillin by intravenous or intramuscular injections at intervals of three or four hours. A few received a portion of the penicillin by continuous intravenous infusion. The use of penicillin locally without simultaneous parenteral administration has been ineffective. When used in conjunction with systemic therapy, local administration of penicillin may offer certain advantages. Since sequestrums have no blood supply, penicillin from the blood stream reaches bacteria present in sequestrums with difficulty. Osteomyelitic cavities within sclerosed bone, although partially vascularized, present a similar problem, since penicillin will not diffuse into such areas from the blood stream in adequate concentration. Local circulation is also impaired in soft tissue scars and sinus tracts. As a result of these considerations, all sinus tracts and all scar and granulation tissue were excised as far as was possible. Osteomyelitic cavities that were suspected of being the site of active infection were exposed and thoroughly curetted. A window to permit curettage was made in the bone, but the cavities were not saucerized. The surgical procedure made the operated area a relatively closed system, with penicillin reaching it both from the blood stream and through catheters.

In this fashion it was possible to maintain a constant high concentration of penicillin at the site where it was most needed. Penicillin, by inhibiting the growth and multiplication of bacteria, will arrest the infection in a high percentage of cases and thus allow healing to take place. In only a small percentage of cases does the use of penicillin fail to produce significant improvement.

- *Mumps with Presternal Edema. S. S. Gellis and M. Peters.—p. 241.

Treatment of Yaws with Penicillin.—Whitehill and Austrian direct attention to the fact that recent laboratory and clinical investigations have produced results which suggest strongly the potential value of penicillin in the treatment of diseases caused by spirochetes and closely allied organisms. Patients with yaws treated with penicillin were admitted to the wards of a British colonial service hospital for observation during and after the period of treatment. The total dosage of penicillin employed was set at approximately 500,000 units; 15,000 units was given intramuscularly every four hours day and night for five to six days. The drug solution was made daily by dissolving the dry powder in enough sterile isotonic solution of sodium chloride to produce a concentration of 10,000 units of penicillin per cubic centimeter. Seventeen cases of primary and secondary yaws from which *Treponema pertense* was isolated by dark field examination have been treated with penicillin. The drug caused disappearance of *Treponema pertense* from the cutaneous lesions within sixteen hours in 16 cases and within forty hours in 1 case. Penicillin therapy brought about complete healing within three weeks of all the cutaneous manifestations of yaws with the exception of one lesion, which failed to epithelize because of local scar formation. During the short period of observation penicillin did not affect significantly the serum Kahn reaction in yaws.

Mumps with Presternal Edema.—Gellis and Peters report observations on 502 patients with mumps admitted to the station hospital at Fort Benning, Georgia, in the spring of 1944. Of these patients 30 exhibited presteral edema. The outbreak involved young army inductees from Southern rural areas and did not appear to be of unusual severity. The onset of the edema was noted on the average of 5.8 days from the appearance of glandular swelling and lasted on the average five days. The lower border of the edema invariably assumed the shape of a necklace and extended downward to a point ranging between the third interspace and the xiphoid process. Laterally the edema extended an equal distance on the two sides of the sternum, varying from a point 3 cm. from the edge of the sternum to the midclavicular line. The edema usually reached its height on the second day after its onset. In 3 patients the skin of the involved area assumed a dull red hue. Only 5 patients developed symptoms coincident with the edema; 2 complained of dysphagia of about twenty-four hours' duration, another of hoarseness, and 2 of tenderness over the sternum when pressure was applied. All patients were afebrile at the time of the edema. The frequency of orchitis was no greater in the group of 30 patients than in the remaining 472 patients. The authors think that obstruction to lymphatic drainage by the swollen glands is responsible for the presteral edema.

Chronic Gastritis and Carcinoma of Stomach.—Warren and Meissner discuss observations on the mucosa of 356 stomachs which were completely or partially removed for gastric carcinoma or for peptic ulcer. They found that chronic gastritis is a labile condition which may regress and which need not necessarily progress. Not all stages or types of chronic gastritis can be considered to be precancerous. The microscopic changes in chronic gastritis should be divided into exudative and epithelial, the former having no direct significance as a precancerous lesion. When epithelial changes become severe they may be comparable to well recognized premalignant lesions elsewhere in the body. Since one stage of chronic gastritis meets the necessary criteria for a precancerous lesion, it may be assumed that some gastric cancers arise on this basis.

Disorders of Liver Associated with Cutaneous Xanthomas and Hyperlipemia.—Eusterman and Montgomery report the history of a woman aged 48 who came to the Mayo Clinic in May 1941 complaining of severe, refractory generalized intense pruritus, continuous aching pain and hyperesthesia, especially in both extremities, cutaneous yellow nodules, gastrointestinal disturbances, loss of weight and strength, yellowing discoloration of the skin, and severe physical and nervous exhaustion. Physical examination disclosed icterus, anemia and cachexia of moderate degree in addition to a generalized xanthochromia, especially of the forehead, face, neck and thorax. Yellow nodules were present on the buttocks, lower part of the back, upper part of the thigh, elbows and both cheeks. Nodules and infiltrated plaques were present on the extensor surfaces of the legs, achilles tendons and eyelids. There were yellowish infiltrations demarking the creases of the palms, as well as discrete nodules on the palms and soles. The liver was firm, insensitive, not especially nodular and considerably enlarged. Although the feces were normal in color, biliuria was present. The serum bilirubin was 5 mg. per hundred cubic centimeters and there was a direct van den Bergh reaction. The bromsulphalein test disclosed retention of the dye grade 4. The albumin-globulin ratio was lowered, and severe hyperlipemia was present. A tentative diagnosis of xanthomatous biliary cirrhosis was made, and the prognosis was regarded as unfavorable. The treatment consisted of a high carbohydrate, high protein, minimal animal fat diet in addition to vitamin concentrates, iron and liver extract. In addition, 1½ ounces (45 Gm.) of a preparation of lipocaic was administered daily. Moderate improvement was followed by slowly progressive decline. Death occurred after three days of coma, presumably hepatic, and massive terminal gastroenteric hemorrhage. The authors emphasize that the hyperlipemia was very severe; the values for the plasma phospholipids and the plasma cholesterol were many times the normal values. The relative values for the various lipids was consistent with Thannhauser and Magendantz's concept of essential xanthomatosis as seen in so-called xanthomatous biliary cirrhosis. From the cutaneous standpoint this case substantiates a previous statement by one of the authors that involvement of the palms and soles is a frequent accompaniment of xanthomatosis associated with hepatic disease. The authors stress that cutaneous xanthomas and hyperlipemia occasionally occur in association with primary disease of the liver, so-called xanthomatous biliary cirrhosis, and in association with hepatic disease that is secondary to obstruction of the common bile duct, especially as the result of postoperative stricture. In cases in

which the hepatic disease is primary, the prognosis is generally unfavorable. It is more favorable in cases in which the underlying pathologic process is due to obstruction of the common bile duct. The exact cause of cutaneous or systemic xanthomatosis remains to be determined.

Sterile Pyuria.—There exist several theories regarding the etiology of the so-called sterile pyuria. Evidence at present points to some gram positive coccus which is difficult to grow and hard to find in stained smears. The sulfonamides, usually so effective in coccic as well as in bacillary infections, are of little avail in this condition. Briggs thinks that, as Wildbolz

suggested, some of the arsenicals should be used for every patient presenting symptoms of renal tuberculosis unless a definite diagnosis has been made by finding the tubercle bacillus, by guinea pig inoculation or by pyelographic evidence of that disease. Other less toxic drugs should be tried before resorting to an arsenical. The author reports 4 cases in which neoarsphenamine was employed with good results. The disease is probably not due to a virus, because virus diseases do not respond to the arsenicals. It is seldom cured by the urinary antiseptics, including the sulfonamides. It responds to the arsenicals sometimes in a spectacular manner.

*Health Hazards Associated with the Welding Process. R. W. Quinn.—p. 410.
*Biologic False Positive Serologic Blood Tests Following Stimulating Dose of Tetanus Toxoid. L. L. Heimoff.—p. 419.

Health Hazards in Welding.—Quinn reports that 6 members of a light cruiser became suddenly ill. A common prodromal symptom was a sweetish taste for an hour or more preceding a severe substernal pain. This pain was followed or accompanied by general malaise, a severe chill, nausea and vomiting, and great weakness. The temperature rose from 2 to 5 degrees F. In 3 of the patients there was evidence of respiratory embarrassment, including dyspnea, cyanosis and orthopnea. In 2 symptoms and signs of acute pulmonary edema appeared, necessitating the administration of oxygen to 1 for several hours. On the following morning the temperature had returned to normal and the men felt much better. There was some remaining substernal soreness, headache and malaise but after a day or two at bed rest they were able to return to duty. The etiology and nature of this disease remained a mystery until it was discovered that the one feature common to all of the cases was a history of exposure to welding fumes on the day of onset of their illness. Each of these men had been exposed to a high concentration of welding fumes for at least a four hour watch in compartments where there was no ventilation. Questioning of the yard workers who were doing the welding revealed that it was caused by fumes resulting from galvanized metal welding and could be prevented by drinking a pint or a quart of milk. Classic metal fume fever is believed to be caused by inhaling tiny metal particles in the form of metallic oxides. Breathing nitrous gases which also are formed in the welding arc may produce a much more serious disease in the form of acute pulmonary edema, pneumonia or bronchitis. Deaths have been reported from this cause. Other injuries which may occur in welding are an acute form of keratoconjunctivitis, burns and electric shock. X-ray changes may occur in the lungs which closely resemble those of silicosis; however, there does not seem to be any change of function associated with these changes even after twenty years of welding. Conscientious observance of safety precautions will prevent accidents. The treatment of metal fume fever is purely symptomatic. Acute pulmonary edema may be a real emergency.

False Positive Serologic Tests Following Dose of Tetanus Toxoid.—Heimoff directs attention to the increased frequency with which false positive serologic reactions for syphilis are encountered. The author has recently had under observation 8 cases with biologic false positive serologic reactions. These cases were interesting in that the only common factor to all of them was that recently a stimulating dose of tetanus toxoid had been administered. The 8 cases cited should

give medical officers cause for delay before starting antisyphilitic treatment merely on the basis of one or two positive Kahn tests. It will be noted that the Wassermann reaction remains either negative or doubtful in all of these false positive reactions. Whether this is due to a truer specificity of the Wassermann test or to a lack of sensitivity in this test, the desirability for having confirmatory Wassermann tests along with a positive Kahn test should be self evident. The author emphasizes that in persons with negative clinical findings, negative history and positive Kahn tests careful questioning as to recent immunization procedures or febrile condition may give the clue to the cause for the positive serologic test.

Photofluorography for Chest Surveys. M. W. Mason.—p. 499.

Axial Projection of Petrous Bone in Chronic Mastoiditis.—According to Danielius the pathologic process of chronic mastoiditis is most frequently established within or near the mastoid antrum and tympanic cavity. Good roentgenographic demonstration of these structures is of paramount importance, but it is rarely if ever obtained by means of the routine projections. Recently the cranially eccentric base views of Steward and Chamberlain-Towne have been recommended for problems concerning the mastoid antrum. In the author's experience, however, these do not display the wealth of detail and convincing clarity of the projection described some twenty-odd years ago by Mayer of Vienna. This view is technically difficult and intricate and the distortion of the temporal bone, with the exception of the antrum, tympanic cavity, external auditory meatus and venous sinus, is considerable. Moreover, Mayer's instructions for placing the patient and arranging the tube and film cassette are difficult to follow. The author describes the positioning of the patient and the arrangement of tube and cassette. He describes and illustrates the anatomic and technical features of the axial projection of the petrous bone. On the basis of cases corroborated by operation, he illustrates the different types and degrees of chronic inflammatory changes at the mastoid antrum. There are several important limitations in diagnostic interpretation: 1. Roentgenographic differentiation of an undeveloped, diploic, not diseased mastoid from a chronic sclerosing mastoid without antrum enlargement is not possible on purely roentgenologic criteria. 2. A cholesteatoma which has attained a considerable size is easily diagnosed as such during the quiescent stage by its smooth, regular borderline. During an acute exacerbation this distinct borderline becomes dissolved and blurred, thus making

a differentiation between a granulomatous, purulent enlarged antrum and a cholesteatoma in the stage of acute exacerbation impossible. 3. A postoperative defect may at times present an appearance similar to that of cholesteatoma. In typical cases, however, the roentgenologic aspects are such that the roentgenologist can stand his ground even if the otologist should at first be of a contrary opinion.

Rocky Mountain Spotted Fever.—Fletcher and Lynch report a case of Rocky Mountain spotted fever in a girl aged 2½ years. On the day after admission, intramuscular injections of penicillin were begun, 5,000 Oxford units being given every hour for five days until a total of 200,000 units had been given. The temperature during all this time averaged 102 F. and returned to normal with complete recovery nineteen days after the onset or eleven days after the beginning of penicillin treatment. Penicillin apparently had no effect on the course of the disease.

Hyperthermia as Manifestation of Neurocirculatory Asthenia.—Friedman attempted to determine (1) the frequency, nature and identifying characteristics of hyperthermia frequently found in neurocirculatory asthenia and (2) the effect of various agents and stimuli on the temperature of such hyperthermic patients. His studies were made on 30 soldiers of an average age of 26 years who manifested symptoms of neurocirculatory asthenia. The diagnosis was made when symptoms of fatigue, dyspnea on slight exertion, palpitation and precordial pain were experienced by a patient who, in addition, exhibited signs of a neurovascular disorder (facial flush, cold, wet hands, labile pulse, dermatographism, tremor of outstretched hands and inability to refrain from respiration for over thirty-five seconds) but no indications of organic disease. A patient with the syndrome of neurocirculatory asthenia was considered hyperthermic if his oral temperature was found to be 99.2 F. or above on more than three occasions during ten days of observation. Eleven of the 30 patients were found to exhibit an episodic type of fever accompanied by moderate tachycardia, increased tremor, local-

ized perspiration and coldness of the skin of the extremities. Despite extensive clinical, laboratory and roentgenographic investigations, no evidence of infection was found in any of the hyperthermic patients. The character of the fever was found to differ in certain respects from that of fever observed in patients with a typical chronic infectious process. The hyperthermic patients also exhibited during their febrile periods significantly different clinical conditions than those usually found in febrile patients suffering from chronic infectious disease. Epinephrine hydrochloride, amphetamine sulfate, citrated caffeine, typhoid vaccine and psychic stimuli were found capable of inducing elevations of temperature in these patients during normally afebrile periods. No sedative, however, was found which was capable of preventing or reducing their febrile reactions. The fever with its accompanying signs observed in these patients is thought to result from abnormal activity of the hypothalamus.

Physiologic Effects of Drinking Undiluted Sea Water.

—Elkinton and Winkler cite cases of shipwrecked persons who died after drinking undiluted sea water. The mind was usually affected, and suicidal attempts were common. The clinical syndrome following the ingestion of undiluted sea water is one in which disturbances of the central nervous system predominate. Modern views seek to relate the ill effects of the drinking of sea water to its hypertonicity, it being a salt solution with an average concentration of 3.5 per cent. Experiments with human and animal subjects following the ingestion of hypertonic saline solution suggest a reasonable tentative explanation of the deleterious and ultimately fatal effects of this procedure. Persons deprived of fresh water can drink little if any sea water without becoming further dehydrated. This dehydration at first affects both intracellular and extracellular fluid. With persistent drinking of sea water dehydration of the cells progresses much more rapidly than does that of the extracellular space, the volume of which is maintained by the retention of sodium chloride. Ultimately extreme intracellular dehydration produces disturbances of the nervous system with terminal respiratory failure, while the absence of extracellular depletion permits the circulation to function adequately until the end. It has been urged that castaways emulate seals, which do not drink sea water but meet their water requirements entirely from the body fluids of fish. The extensive promotion of this emergency measure has far outstripped its experimental investigation. While entirely reasonable from the point of view of salt excretion, since concentration of salt in the body fluids of fish is nearly isotonic, it ignores the fact that much urea is formed from the protein of fish and that this urea requires extra water for its excretion. Ingestion of fish does not ameliorate dehydration in human beings, since all the water in the fish is required for the excretion of the urea. Seals, like dogs, presumably can excrete the urea with a smaller volume of water and can so retain some of the water for other purposes.

Bacillary Dysentery.—Hurevitz shows that in this as in other wars bacillary dysentery is one of the most significant causes for disability among soldiers. He presents an analysis of the cases of 1,120 soldiers who were admitted to an overseas station hospital with the diagnosis of diarrhea or dysentery during the period between May 1 and November 1. Five hundred and eighty-seven had stool cultures positive for dysentery bacilli, of which 409, or 69.8 per cent, were positive for *Shigella* paradyserteriae. The symptoms ranged from extremely mild manifestations to severe toxemia. Treatment in all cases was carried out with either sulfaguanidine or sulfadiazine. Special emphasis was placed on adequate fluid intake and nursing care. All patients recovered from the dysentery infection. One patient died, but at necropsy he was found to have had bacterial endocarditis with old rheumatic aortic and mitral lesions.

Insomnia.—According to Jones, insomnia is the symptom most frequently complained of by patients with nervous and mental disorders. Sleeplessness often precedes the appearance of other signs of nervous or mental disorder, and in young persons prolonged insomnia should arouse suspicion that a psychoneurosis or psychosis is imminent. The majority of patients with insomnia suffer no physical reaction to prolonged sleeplessness. Little sleep is required to remove the effects of fatigue and to maintain life. There are two kinds of sleep, one being physiologic and essential for the maintenance of life and the other being psychologic and its amount being determined by habit and custom. Psychic reactions to sleeplessness are not the direct result of lack of sleep but represent the patient's emotional response to deprivation of a customary mode of escape. The secondary psychic results of insomnia are irritability, inability to concentrate, loss of interest and depression. Like other neurotic symptoms, insomnia may have value to the patient as an alibi for the evasion of duties or responsibilities. In most neuroses and in anxiety states, sleep is inhibited by patients' filling their minds with emotional thoughts, by worries and by preoccupation with the idea of inability to sleep. Sleep is delayed by grief and worries, by fear and by anxious expectation. Total or absolute insomnia is rare in the neuroses. It is seen in the psychoses, in acute mania and melancholia and in toxic and confusional states. In neurasthenia, patients experience difficulty in getting to sleep and often awake suddenly, sweating and trembling. In hypochondriasis sleeplessness sometimes constitutes the focus of fixation of the patient's interest. Persistent insomnia is sometimes indicative of simple depression (melancholia). The essential preliminary to treatment is a careful estimation of physical and psychologic factors that have a bearing. The first essential in psychotherapy is persuading the patient to adopt a correct mental attitude to his sleeplessness; his mind must be disabused of the common belief that lack of sleep is followed by grave consequences. Nervous patients should not retire too early and should avoid sleeping during the daytime. They must learn to abandon their mental activities when they retire. Heavy meals and stimulating drinks should be avoided before retiring. When insomnia is absolute,

as in acute mania, delirium tremens or confusional psychoses, there is a temptation to use dangerous doses of powerful hypnotics. It is, however, better to repeat safe dosage than to give larger initial doses. The barbiturates represent the most useful class of hypnotic drugs; they are well tolerated, act rapidly, leave little "hangover" and have little habit forming tendency. It will be found desirable to change the drug from time to time.

Procaine Infiltration of Greater Occipital Nerves in Ophthalmic Cephalalgia.—Papilian and his associates report 5 cases of severe headache resulting from diseases of the eye, particularly of the glaucoma type, in patients between the ages of 29 and 70 years. Procaine hydrochloride infiltration of the two great occipital nerves was performed, 15 cc. of 1.2 per cent solution of the drug being injected into each nerve. Relief resulted within a few hours and the severe headache disappeared completely within twenty-four hours in 4 of the cases in which hemicrania was associated with subacute iridocyclitis, contusion of the eyeball and subluxation of the crystalline lens and with leukoma adherens and secondary glaucoma. The headache recurred within forty-eight hours in 1 case of left hemicrania associated with leukoma adherens and painful secondary glaucoma of the left eye. Procaine hydrochloride infiltration was repeated and the headache disappeared. The analgesia continued, and the patients were dismissed on their own request but warned to return to the hospital if the headache recurred. The therapeutic results of the anesthesia of the large occipital nerves were the same in all the cases although they differed anatomically. The pain disappeared but its cause was not removed. A definite tendency to recovery was observed and may be explained by the disappearance of the irritative pain factor.

Gunshot Coxitis. M. O. Fridland.—p. 32.

Treatment of Gunshot Wounds of Large Joints.—Molodaya reports 923 cases of gunshot wounds of the larger joints treated in an evacuation hospital. There were 472 instances of gunshot injuries of the knee joint, of which 290 (61 per cent) were treated conservatively. In all, 182 operations were done. The postoperative mortality amounted to 3.8 per cent, while the general mortality amounted to 1.4 per cent. The conservative treatment of knee joints consisted of a circular plaster of paris cast with inclusion of the pelvis. To prevent atrophy of the muscles and contractures the cast was removed in from ten to fourteen days and therapeutic exercises were practiced. Resection of the knee joint without drainage was found to be the operation of choice for gunshot wounds of the knee joint complicated by fractures and osteomyelitis. Ollier's subperiosteal resection resulted, as a rule, in regeneration of bone from the periosteum and in elongation of the femur. Early resection or disarticulation is indicated in gunshot injuries of the hip joint in the majority of instances. Prophylaxis of postoperative shock consists in substitution of local anesthesia for general narcosis, preliminary ligation of the femoral artery and transfusion of large amounts of blood into the femoral vein at the beginning and at the end of the operation. The best treatment for gunshot wounds of the elbow joint complicated by fractures is early subperiosteal resection with early therapeutic exercises.

Book Notices

Lectures on the Kidney. By Homer W. Smith, A.B., Sc.D., M.S., Professor of Physiology and Chairman of the Physiology Laboratories, New York University College of Medicine, New York. Porter Lectures Series IX. Delivered at the University of Kansas School of Medicine, Lawrence, Kansas City. The William Henry Welch Lectures Delivered at the Mount Sinai Hospital, New York City. Cloth. Price, \$1. Pp. 134, with 13 illustrations. Lawrence, Kansas: University Extension Division, University of Kansas, 1943.

In this book are brought together the three Porter Lectures given in 1939 and the two William Henry Welch Lectures delivered in 1943 by Dr. Homer W. Smith. The first lecture, on the "Evolution of the Kidney," is a fascinating story of the accommodation of the kidney, in both structure and function, to the changing conditions of successive geological revolutions, periods and eras. Inherent in this story are the teleological reasonings and imaginative explanations so necessary to fill in the gaps where evidence is lacking. One of the conclusions reached is that in structure and function the human kidney differs only in details from that of the dog and some other animals and that its closest analogue in function is in the kidney of the great apes. Although much about renal function in general has been learned from studies on the frog, yet the results of those made on the dog are more directly applicable to the problem of renal function in man. This lecture provides a good introduction to the lectures that follow. The remaining four lectures, which deal in great part with the studies of Homer Smith and his collaborators, show how much more can be learned about renal function in man from direct observations on man. The lecture on "Renal Physiology Between Two Wars" gives the more immediate background for these studies, which involved the development of special methods for the estimation of renal function in health and disease and especially in the hypertensive state. The author and his collaborators, not content with the mere estimation of total renal function, devised methods whereby they were able to determine, at least approximately, the amount of blood flow through the kidneys and the part played by filtration through the glomeruli and excretion and reabsorption through the tubules in the final production of urine. The last three lectures give the results of these studies in considerable detail and cannot be summarized in a review of this kind. It is necessary to read the publications and become familiar with the newer methods and terminology in order to be able to evaluate the results of these studies and the conclusions reached. The book gives the reader the information necessary to familiarize him with the large series of publications which these lectures represent.

Speech Reading—Jena Method: A Textbook with Lesson Plans in Full Development for Hard-of-Hearing Adults and Discussion of Adaptations for Deaf and Hard-of-Hearing Children. By Anna M. Bunker, Instructor of Speech Reading, Department of Special Education, Michigan State Normal College, Ypsilanti, Michigan. Revised edition. Cloth. Price, \$2.50. Pp. 136. Danville, Illinois: The Interstate, 1944.

The title of this textbook may be puzzling to the uninitiated. It is a synonym for what is more commonly termed "lip reading." The book is a revised edition of mimeographed material published in 1932 by Miss Bunker and Miss Bessie L. Whitaker, both of Michigan State Normal College at Ypsilanti, Mich. The general format and presentation of material follow the theories developed at Jena, Germany, by the late Dr. Karl Brauckmann. These theories have been developed and tested over a period of some twelve years by Miss Bunker and her associates. Miss Bunker points out that "listening has been too long . . . considered a purely auditory affair" and that the progressive teacher of speech reading should emphasize the aspects of "sharp observation" and hearer-responsiveness to the spoken word. For this reason, she feels that her book presents material valuable to all students of oral communication.

Lesson plans are mapped out to develop kinesthetic awareness of speech movements and ability to imitate the speaker, to stress development of syllable drills (including word, phrase and sentence series) and to develop a sense of rhythmic coordination of the spoken and the auditory process.

There is much excellent material in the book, but it suffers from a confusing presentation and a paucity of explanation. To cite one example, the author uses several symbols to indicate various rhythmic patterns but nowhere explains the respective

significations of the symbols; in consequence, the reader is forced to puzzle them out for himself. Adding to the confusion is the fact that, although the book is written in the third person, the author frequently shifts to the role of the speech reading teacher giving instructions to her pupils. There are no quotation marks or variations in typography to indicate the shift to direct conversation. Despite these criticisms, Miss Bunker's textbook should be valuable to those who teach lip reading. In addition to a series of suggested lesson plans, it contains a list of words most commonly used, a brief index and a helpful bibliography.

Theory of Occupational Therapy. By Norah A. Haworth, M.A., M.R.C.S., L.R.C.P., Assistant Medical Officer, London Passenger Transport Board, and E. Mary MacDonald, Principal, Dorset House School of Occupational Therapy, Barnsley Hall Emergency Hospital, Bromsgrove. With foreword by Sir Robert Stanton Woods, M.D., F.R.C.P., Consultant Adviser in Physical Medicine to the Ministry of Health. Second edition. Fabrikoid. Price, \$2.50. Pp. 148, with 68 illustrations. Baltimore: William Wood & Company, 1944.

The authors include in occupational therapy "any work or recreational activity, mental or physical, definitely prescribed and guided, for the distinct purpose of contributing to and hastening recovery from disease and injury." The relationship of occupational therapy to other forms of physical medicine is clearly stated in the preface by Sir Robert Stanton Woods, consultant adviser in physical medicine to the Ministry of Health in London.

This book was written primarily for students and nurses. Its elementary character and brevity preclude its use as a textbook, but prospective students will find it very helpful. It is also an excellent introduction for the many physicians in America who are beginning to become interested in occupational therapy. Throughout the book there are many practical applications of this form of treatment for patients in general hospitals, tuberculosis sanatoriums and mental wards.

The book, written and printed in England, contains chapters on training, bibliography and finance that are not pertinent to conditions in the United States. Furthermore, educational programs in America include a greater amount of training and more careful standardization and accrediting. Nevertheless the chapters on equipment, apparatus and materials and records and prescriptions are quite valuable.

Physiology in Health and Disease. By Carl J. Wiggers, M.D., D.Sc., F.A.C.P., Professor of Physiology and Director of Physiology Department in the School of Medicine of Western Reserve University, Cleveland, Ohio. Fourth edition. Cloth. Price, \$10. Pp. 1,174, with 247 illustrations. Philadelphia: Lea & Febiger, 1944.

Much recent progress in physiology has been due to the special studies associated with war problems. This edition has recognized that fact and has added or revised its discussions of nerve degeneration, eye fatigue, color appreciation, camouflage, dark adaptation, auditory efficiency, somatic and visceral pain, auditory efficiency, principles of transfusion, blood substitutes, hemorrhage and shock, artificial respiration, dietary deficiencies, physical fitness and fatigue, water deprivation, acclimatization, altitude, air and seasickness and other sections as well. Approximately one third of the text has been completely rewritten, and other sections have been significantly altered. It is consequently apparent to how great a degree the knowledge of this fundamental science has been subject to recent change and how successful the author is in keeping this authoritative textbook abreast of advances in the field.

The Gastro-Intestinal Tract: A Handbook of Roentgen Diagnosis. By Fred Jenner Hodges, B.S., M.D., Professor of Roentgenology, University of Michigan Medical School, Ann Arbor, Michigan. Cloth. Price, \$5.50. Pp. 320, with illustrations. Chicago: Year Book Publishers, Inc., 1944.

The author has contrived to put into this little handbook a readable and comprehensive discussion of gastrointestinal radiology. The illustrations are exceptionally well done and are grouped in such a way that several roentgenograms illustrative of an individual case are presented side by side on the same page, thus facilitating comparison. The reader is made to appreciate that in the gastrointestinal tract fluoroscopy is an important adjunct of the x-ray examination, offering as one of its chief advantages the opportunity to make "aimed" roentgenograms, sometimes spoken of as "spot films." The author and the publisher have succeeded admirably in the production of a useful handbook covering the digestive tube and the biliary tract.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HIBERNATION

To the Editor:—Will you please send me information on the physiology and pathology of hibernating animals during the period of hibernation. Particularly I should like to know if there is consumption of tissue other than fat to maintain life during the starving of hibernation. Are there pathologic changes following hibernation? It would seem that the normal maintenance of life would require the consumption of all three essentials of normal diet, fats, proteins and sugar or starch. Does sclerosis occur during hibernation, and is it of the fibrosis or calcium replacement type or a degree of both?

A. J. Alcorn, M.D., Chicago.

ANSWER.—Hibernation is the ability of certain homoiothermal (warm blooded) animals, deprived of food and exposed to the cold, to revert to the poikilothermal (cold blooded) state, thus making their supply of fuel (fat) last through the winter season. Their metabolism is, in the main, that of starving nonhibernating animals, accentuated by the depressing effect of low temperature on all body functions. The respiratory quotient during hibernation is even lower than in ordinary starvation, suggesting that fat is the principal if not the only source of energy. The blood sugar is said to be lower than normal, with insulin injections favoring the onset of hibernation. There is a drop in total phosphorus and in acid insoluble phosphorus in the blood, as well as an increase in the potassium-calcium ratio. A liberal supply of vitamin D was found to hinder hibernation.

Adrenalectomy, as rapidly fatal to hibernating animals as to other mammals during the summer season, has no effect during hibernation. Other changes in the endocrine glands have been reported, including the presence of certain substances in the "brown fatty tissue," known as the interscapular or hibernating gland. Extracts prepared from that tissue, removed from a hibernating hedgehog, when injected into rats led to a state of depression and a drop of 20 to 30 per cent in the basal metabolic rate.

No disease appears to follow hibernation, but there is a pronounced hypertrophy of the hypophysis, probably related to the effect of light and responsible for ushering in the spring breeding season.

POTASSIUM BITARTRATE AS POWDER FOR SURGEONS' GLOVES

To the Editor:—Recently there appeared in The Journal an article to the effect that talcum powder should be abandoned as an agent for keeping surgeons' gloves dry. In its place, cream of tartar was advocated. This latter has been utilized in our hospital for some time and has proved to be unsatisfactory because of its caking qualities. Would it not be wise to offer some suggestion as to how these caking qualities may be obviated?

M.D., Connecticut.

ANSWER.—The St. Louis Barnard Skin and Cancer Hospital workers report that they carried out a large series of experiments on the caking properties of potassium bitartrate and found, without exception, that caking did not occur when the powder was sterilized for not more than fifteen minutes at not more than 15 pounds of steam pressure. It may show a tendency toward clumping, but if sachets are used the clumps are readily broken by finger pressure. If, on the other hand, powder shakers are used, mere agitation of the shakers will break up the clumps. These same workers announce that within a reasonable time they hope to see on the market a new process starch powder that does not gel on autoclaving, that is somewhat smoother than the bitartrate and that may prove to be a cheaper product.

ROTARY NYSTAGMUS

To the Editor:—I would appreciate information about the significance of the isolated finding of rotary nystagmus. A Negro woman aged 42 suffers from a recurrent pyelitis. During a routine examination the rotary nystagmus was discovered. The patient herself maintained that she has never been aware of its presence, but inquiry from relatives makes it likely that this nystagmus has been present at least since high school days. A neurologic examination gave results entirely within normal limits except for the nystagmus. There is no history of syphilis, and the Wassermann reaction is normal.

M.D., California.

ANSWER.—Rotary nystagmus may be congenital. It also occurs in cases of poor or defective visual acuity and in ocular muscular weakness. It is seen in acute lesions of the internal ear. It is not a sign of organic disease of the central nervous system.

TRANSPLANTATION OF URETERS FOR EXSTROPHY OF BLADDER

To the Editor:—Is not the transplantation of the ureters the best procedure in exstrophy (atrophy) of the bladder? If any one has had success with plastic operations, please refer me to the articles in the literature. My patient is 15 years of age. The vaginal orifice is at the normal site of the symphysis pubis, which does not appear to be present. The ureteral openings are visible but to date there has been no ascending infection.

D. Guilford Dudley, M.D., Endicott, N. Y.

ANSWER.—Exstrophy of the bladder is best treated by transplantation of the ureters into the sigmoid with subsequent removal of the bladder tissue. The method of inserting the ureters into the bowel most frequently used is that suggested by Coffey with modifications by Dr. C. H. Mayo. Some surgeons transplant the two ureters at the same time. The success of this operation in suitable subjects and in young children has been most encouraging. It is stated that there has been no ascending infection in this patient, in spite of the fact that the ureters are visible. This is a peculiarity of this condition in that ascending infection apparently is prevented by nature's valvelike mechanism in the lower ureter with the aid of ureteral peristalsis.

It would be advisable to make an excretory urogram before operation in order to determine the comparative function of the kidneys and the presence of any dilatation in either ureter or pelvis. The symphysis pubis is usually absent in most children with exstrophy of the bladder. Results of this type of operation are well exemplified in articles by Walters and Braasch (*Am J. Surg.* 23:255 [Feb.] 1934) and by Higgins (Transplantation of Ureters into the Rectosigmoid in Infants, *J. Urol.* 50:657 [Dec.] 1943).

HYPERSENSITIVE NASAL MUCOSA

To the Editor:—A man aged 55 complains of a hypersensitive nose, which at times discharges a large amount of thin mucus. This occurs regularly and profusely at meal times and may occur any time during the day. Under normal conditions the nasal membranes appear slightly pale, the turbinates are normal, the septum is normal and the large sinuses are normal. He does not sneeze, and the nose is never stuffy. I believe that this is a nerve irritation and is in some way connected with the innervation of the salivary glands. I have cauterized the turbinates with no improvement. I should like advice as to treatment.

Carl C. Cowin, M.D., Hollywood, Calif.

ANSWER.—Sneezing, rhinorrhea and nasal blocking are the common symptoms of the hypersensitive nose. It is not necessary for all of these manifestations to be present; one or two may predominate or even be the sole manifestation. Thus we find some people in whom sneezing is a predominant symptom, others in whom blocking of the nasal passages may be the only manifestation, while in still others a profuse rhinorrhea is a sign of the hyperesthetic rhinitis. The patient under question apparently falls in this group. The diagnosis could be corroborated still further by the finding of eosinophils in the nasal smear. It would be wise to regard a patient like this as allergic until proved otherwise. A serious attempt should be made to make an etiologic diagnosis by means of skin tests. If these do not yield results, restricted diets should be tried with a view to determining a food allergy.

DIABETES AND IMPOTENCE

To the Editor:—Have any instances of impotence or diminished sexual desire been observed in man receiving prolonged and high doses of insulin? Is such a condition at all probable?

M.D., California.

ANSWER.—Obviously one sees impotence and diminished sexual desire in man receiving prolonged and high doses of insulin, because prior to the introduction of insulin the average age of diabetic patients was 44 years at death and now is 65 years. If anything, adequate control of the diabetes will improve rather than diminish sexual function. It is true, however, that long continued, poorly controlled diabetes, which implies inadequate use of insulin, may result in impotence in a comparatively young man.

SKIN TESTING FOR ALLERGY

To the Editor:—Can you advise me about the relative values of the patch, scratch and intracutaneous methods of skin testing for allergies? I intend to purchase a new diagnostic set and would appreciate the information.

Allen G. Janecy, M.D., Thief River Falls, Minn.

ANSWER.—The patch, scratch and intracutaneous methods of testing cannot be compared. The patch test is used only for cases of contact dermatitis. The scratch and intracutaneous methods of testing may be compared. Scratch tests will produce positive skin reactions less frequently than intracutaneous tests. They are, however, safer than intracutaneous tests. Intracutaneous tests will produce positive reactions more frequently and are considered more dangerous in the hands of an inexperienced worker than the scratch test technic.

TREATMENT OF STAPHYLOCOCCIC, PNEUMOCOCCIC, GONOCOCCIC AND OTHER INFECTIONS

WITH PENICILLIN

CARL G. HARFORD, M.D.
SAMUEL P. MARTIN, M.D.
PAUL O. HAGEMAN, M.D.
AND
W. BARRY WOOD JR., M.D.
ST. LOUIS

In June 1942 the Committee on Chemotherapeutic and Other Agents of the National Research Council was requested to organize a cooperative clinical study to evaluate the effectiveness of penicillin in the treatment of bacterial infections. A relatively large group of clinics was asked to participate in the investigation in order that adequate data might be accumulated as rapidly as possible. The preliminary results of the cooperative undertaking have been summarized in a recent publication.¹ The present report deals with a more detailed account of the use of penicillin² in the treatment of 103 patients in this clinic. Our experience with penicillin in the treatment of syphilis will be published elsewhere.

METHODS

Selection of Patients.—In this study preference was given to patients with fulminating bacterial infections, particularly those known to be unresponsive to sulfonamide chemotherapy. Less severe infections were treated in a small group of patients known to be hypersensitive to sulfonamides. Thirteen patients with gonorrhea were treated with penicillin after repeated courses of sulfonamide therapy had failed to influence the infection. In general, patients were not accepted for penicillin therapy until the bacterial origin of the infection had been established by culture. In a few cases treatment was begun before the results of cultures were known, but in each instance there was adequate clinical evidence of a specific bacterial infection.

Administration of Penicillin.—The sodium salt of penicillin (usually containing 300 units or more per milligram) was dissolved in isotonic solution of sodium

chloride in concentrations of 5,000 to 20,000 units per cubic centimeter. Only the amount of penicillin needed for twenty-four hours of treatment was put into solution at one time. All penicillin solutions were kept in the refrigerator between injections. Systemic treatment was accomplished by either intravenous or intramuscular injections. In many instances it was found convenient to inject the penicillin into the rubber tubing of a continuous intravenous drip. The dosage employed varied from 5,000 to 40,000³ units every one, two or four hours, depending on the circumstances. The total number of units of penicillin administered in each case depended on the severity of the infection and the relative susceptibility of the causative bacterium to the drug. Treatment was continued over longer periods when clinical response was slow or recurrence seemed likely.

All accessible infected foci were treated by local injections of penicillin. In such cases systemic therapy was given at the same time. Infected wounds were treated by gauze packs saturated in penicillin solution containing 1,000 units per cubic centimeter. Freshly saturated packs were applied at least once a day. Intrapleural injections of 5,000 to 20,000 units every twenty-four hours were used in the treatment of infections within the pleural space. The usual initial intrathecal dose employed in the treatment of meningitis was 20,000 units in 2 cc. of isotonic solution of sodium chloride. Further intrathecal injections were given each day in decreasing amounts and were continued until all signs of meningitis had subsided.

Other Chemotherapy.—It will be noted in the tables and charts that sulfonamide therapy preceded or followed treatment with penicillin in a number of instances. In some cases the infection had progressed in spite of intensive sulfonamide therapy; in others, sulfonamide drugs had been administered before admittance to the hospital. During the early months of the study, when the supply of penicillin was limited, sulfonamides were given in a few cases after recovery to prevent recurrence of infection. In no instance were sulfonamide drugs and penicillin given at the same time.

Clinical Observations.—All patients treated were admitted either to the Barnes Hospital or to closely affiliated hospitals.⁴ Daily visits were made to each patient during the active phase of the illness and complete records were kept in every case. Patients with gonorrhea were retained in the hospital for thirty days after the completion of therapy in order to avoid the possibility of confusing reinfection with relapse. All patients thus far treated have been included in this report. All fatal cases in which autopsies were per-

From the Department of Internal Medicine, Washington University School of Medicine, the Oscar Johnson Institute for Medical Research, and Barnes Hospital, St. Louis.

Barry, Jr.: Penicillin in the Treatment of Infections: Statement by the Committee on Chemotherapeutic and Other Agents, Division of Medical Sciences, National Research Council, J. A. M. A. 122: 1217-1224 (Aug. 28) 1943.

2. The penicillin was provided by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for clinical investigations recommended by the Committee on Chemotherapeutic and Other Agents of the National Research Council.

3. Proportionately smaller doses were employed in the treatment of infants and small children.

4. St. Louis City Hospital, City Isolation Hospital, St. Louis Children's Hospital and the Jewish Hospital of St. Louis.

formed were studied by Dr. Robert A. Moore of the Department of Pathology and will be reported in a separate publication.

RESULTS

Staphylococcic Infections.—The results of penicillin therapy in the treatment of staphylococcic infections are shown in table 1. There were 16 patients with bacteremia; of these all had metastatic pneumonia and 3 were suffering from bacterial endocarditis. In this entire group of patients only 2 died: 1 with bacterial endocarditis and the other with furunculosis of the face, metastatic pneumonia, cavernous sinus thrombosis and acute pericarditis (cases 13 and 14). In addition there were 4 instances in which cultures of the blood failed to reveal staphylococci but in which clinical evidence left no doubt that bacteremia had previously existed (cases 17, 18, 19 and 20). In the latter group there was but one death. Five patients with acute localized infection without bacteremia (cases 21, 22, 23, 24 and 25) were treated with penicillin, and 1 died. There were 6 patients with acute osteomyelitis, 3 of whom

a stiff neck. When first seen in the hospital, on the eighth day, she was comatose, dyspneic, cyanotic and obviously dehydrated. There were an extensive carbuncle of the face with numerous points of drainage, swelling of the eyelids and severe chemosis. Eyegrounds and external ocular movements were normal, but there was definite trismus. Numerous crepitant and sonorous rales were heard at the base of both lungs. Pleural friction rubs were heard bilaterally, and an x-ray plate of the chest showed many patches of consolidation throughout both pulmonary fields. The liver and spleen were both palpable. There was pronounced stiffness of the neck. The spinal fluid contained 80 cells per cubic millimeter, 40 per cent of which were polymorphonuclear leukocytes. The fluid was sterile. Blood culture revealed 70 colonies of hemolytic *Staphylococcus aureus* per cubic centimeter of blood, and the same organism was isolated from the conjunctiva. There was a leukocytosis of 18,000 and an anemia of 3.88 million red blood cells with 11 Gm. of hemoglobin.

Penicillin was administered as shown in figure 1, and gradual improvement took place. The local lesion subsided; the fever fell by lysis, and the pulmonary infiltration decreased. Cerebrospinal fluid on the fourteenth day of the disease contained 12 cells per cubic millimeter. On the twelfth day of illness a pleural effusion was demonstrated in the right chest. The fluid recovered on thoracentesis was sterile and contained 9,300 cells, 69 per cent of which were polymorphonuclear leukocytes. Penicillin therapy was discontinued on the twenty-fourth day of illness, and nine days later a relapse had occurred, as evidenced by high fever, bacteremia and a pleural effusion in the left chest. Further penicillin treatment⁵ resulted in the patient's prompt recovery.

Summary.—A 26 year old woman with staphylococcic bacteremia, extensive metastatic pulmonary lesions and an aseptic meningitis, all resulting from a widespread carbuncle of the face, responded satisfactorily to penicillin therapy. Nine days after the treatment was discontinued the patient suffered a relapse with bacteremia, but recovered completely after a second course of penicillin.

CASE 2.—History.—F. A., a white man aged 54, was apparently well until four days before being admitted to the hospital, at which time he noticed tenderness, redness and swelling of the nose. On the day before entry he began to have chills and fever, and on the following day he complained of severe chest pains exaggerated by respiration. When first seen at the hospital, the whole right side of his face was swollen, as shown in the photograph in figure 2. There was some swelling on the left side of the face also. Although he was given 3.5 Gm. of sulfamerazine shortly after his admission to the hospital, this form of therapy was soon discontinued and on the second hospital day penicillin treatment was started. During the first twelve hours in the hospital his condition rapidly became worse. The percussion note was found to be impaired over both lung bases, where there were heard widespread crepitant and sonorous rales and bronchial breath sounds. Friction rubs were also heard over both lung bases. A roentgenogram of the chest showed patchy consolidation throughout the right lung and in the left lower lung field. Blood cultures showed hemolytic *Staphylococcus aureus*, and the white blood cell count was 17,800. Therapy with penicillin resulted in the patient's steady clinical improvement, the fever subsiding by lysis. On the seventh day of the disease three points of drainage made their appearance on the nose. The material which drained from these areas contained hemolytic *Staphylococcus aureus*. On the twelfth day of illness the penicillin was given intramuscularly instead of intravenously because of thrombosis at the site of a continuous intravenous injection. On the seventeenth day the signs of a pleural effusion were noted, and 485 cc. of serosanguineous fluid containing hemolytic *Staphylococcus aureus* was removed by thoracentesis. The penicillin was instilled into the pleural cavity at the time of the thoracentesis, and additional intrapleural injections of penicillin were given on the twentieth and twenty-fifth days. Recovery.

had a complicating bacteremia (cases 10, 18 and 19). Surgical operation was carried out in only 3 of these cases. All of the patients were obviously benefited by penicillin therapy, none of them having sustained a recurrence of the infection several months after treatment.

The therapeutic response in chronic osteomyelitis was less encouraging. Four of 7 patients treated were improved, 2 received at least temporary benefit and 1 patient has gone for more than twelve months without drainage from the original sinus.

The following case reports illustrate the effectiveness of penicillin in the treatment of severe staphylococcic infections:

CASE 1.—History.—B. B., a white woman aged 26, "picked a pimple" on her left cheek eight days before entering the hospital. On the following day she had a chill, and the inflammatory process spread over the entire left side of her face. She was treated with cold moist applications to the face and two tablets of a sulfonamide drug every three hours. In spite of this therapy the local lesion continued to spread and chills continued. On the seventh day of the illness the patient developed

5. On the thirteenth day of illness at the time when the left pleural effusion was demonstrated, 10,000 units of penicillin (not shown in figure 1) were instilled into the pleural cavity.

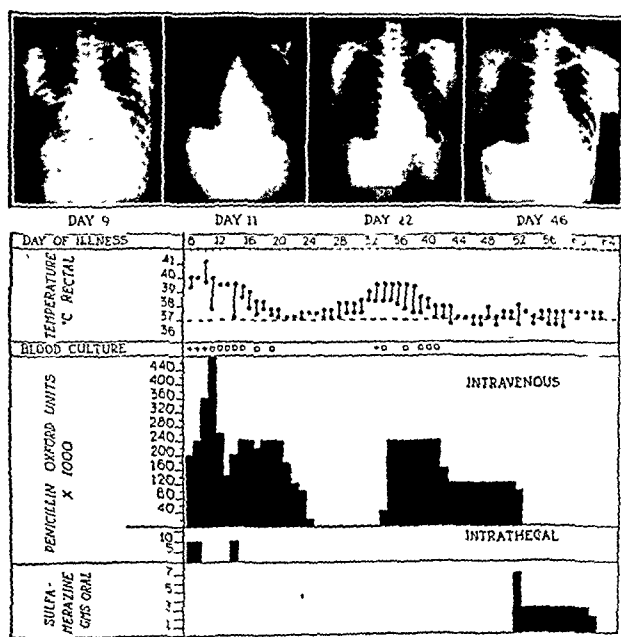

Fig. 1.—Staphylococcic infection, with pulmonary infiltration.

following the first thoracentesis, was uneventful, and an x-ray film of the chest taken at the time of discharge showed only pleural thickening and adhesions.

Summary.—A man aged 54 with staphylococcal furunculosis of the nose and cellulitis of the face was treated with penicillin after bacteremia, metastatic pneumonia and bilateral pleurisy

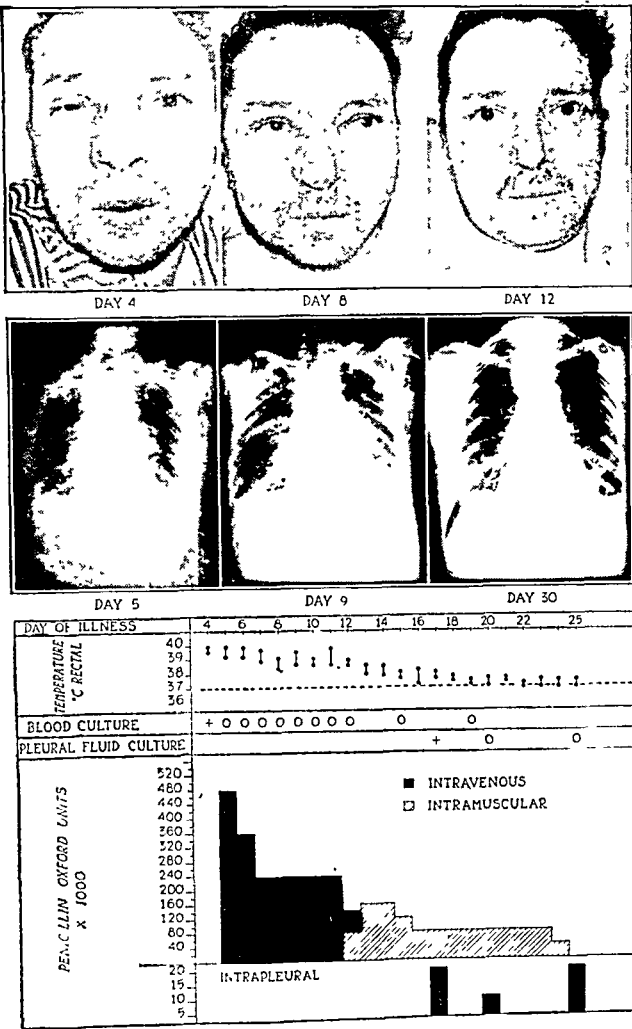

Fig. 2.—Severe staphylococcal infection of face, lungs and pleura.

had developed. An infected pleural effusion was detected on the seventeenth day of illness and was treated with instillation of penicillin into the pleural space together with continued parenteral penicillin therapy. The patient's recovery was complete after twenty days of penicillin treatment.

CASE 8.—History.—A. Y., a girl aged 2 years, entered St. Louis Children's Hospital⁶ after an acute onset of fever and vomiting six days before. On the day preceding admission her right ankle became swollen, red and tender, and she was given 1.75 Gm. of sulfathiazole. When first seen in the hospital she was semistuporous and was obviously acutely ill. Her temperature was 41 C. (105.8 F.); respirations were labored, and there was pronounced stiffness of the neck. No abnormalities of the heart or lungs were noted on either physical examination or fluoroscopy. The tip of the spleen was just palpable, and there were signs of acute inflammation in the region of the right ankle. The leukocyte count was 15,000, with many young forms noted in the differential count. X-ray films of the right ankle showed only delayed development of centers of ossification. The spinal fluid was normal. Culture of the blood showed 212 colonies of hemolytic *Staphylococcus aureus* per cubic centimeter. On entry the patient was given 1.2 Gm.

6. This case is reported through the courtesy of Dr. Alexis Hartmann.

of sodium sulfapyrazine, but on the following day pustules were noted over the entire body, the patient was comatose and sulfonamide treatment therefore was replaced by penicillin therapy (fig. 3). On the same day, incision of the ankle revealed an abscess adjacent to the os calcis but there was no osteomyelitis.⁷ Culture of the exudate showed hemolytic *Staphylococcus aureus*, and penicillin was applied to the wound on a gauze dressing. On the ninth day of the disease a pericardial friction rub was heard, and on the following day fluoroscopy showed enlargement of the heart. On this day the liver became palpable, and there appeared edema of the lower extremities. By the eleventh day the child was more alert, but pulsations of the heart were no longer visible under the fluoroscope. On the fifteenth day 105 cc. of turbid fluid containing hemolytic *Staphylococcus aureus* was removed from the pericardial cavity and penicillin was injected directly into the pericardial sac. This procedure was repeated on subsequent days until sterile straw colored fluid was obtained. The patient's condition gradually improved, and her course in the hospital thereafter was uneventful except for a short bout of fever associated with transient diarrhea. When seen one hundred and thirty-one days after the onset of her illness she was apparently completely well.

Summary.—A girl aged 2 years with severe staphylococcal bacteremia, an abscess of the heel, multiple pustules of the skin and staphylococcal pericarditis made a complete recovery following surgical drainage of the abscess and intensive systemic and local penicillin therapy.

CASE 10.—History.—W. H., a schoolboy aged 13 years, jumped from a tree and complained shortly thereafter of pain in the right hip. He felt poorly during the next two days and by the fourth day became semicomatose, with a fever of 40.8 C. (105.4 F.). He was sent to a hospital in western Missouri, where an x-ray plate of the hip showed no destruction of bone but culture of the blood disclosed hemolytic *Staphylococcus aureus*. He was given sulfathiazole with an initial dose of 1 Gm. followed by 0.5 Gm. every four hours. In spite of this therapy the temperature of 38 to 41 C. (100.4 to 105.8 F.) persisted and he remained in coma. When first seen in the Barnes Hospital, his lungs were clear and his heart was normal except for a systolic murmur at the apex. Neither spleen nor

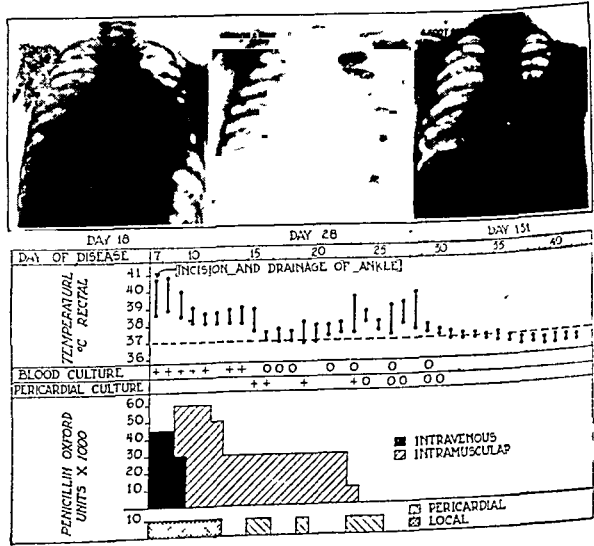

Fig. 3.—Staphylococcal pericarditis responds to drainage and penicillin

liver was palpable. The right thigh was swollen, and passive motion of the leg caused pain. There were also swelling and slight redness of the right ankle. The leukocyte count was only 11,500, but there were many young forms seen in the differential count. X-ray films of the hip, thigh and ankle showed no lesions of the bone, but the blood contained 140 colonies of hemolytic *Staphylococcus aureus* per cubic centimeter

7 The operation was performed by Dr. Peter Heinbecker.

and therapy with penicillin was begun immediately (fig. 4). Although the patient's condition improved and roentgenograms of the hip on the twelfth day failed to show osteomyelitis, both the fever and the bacteremia persisted. Three hundred and fifteen thousand units of penicillin in twenty-four hours was therefore administered, and thereafter the fever subsided and

Fig. 4.—Treatment of patient with acute osteomyelitis

bacteria could no longer be cultured from the blood. By the sixteenth day the patient had apparently recovered, but the supply of penicillin was exhausted; hence sulfamerazine was administered to prevent a possible recurrence of the infection. Hematuria was noted on the twenty-fifth day, but it subsided when sulfamerazine was discontinued. There followed a toxic psychosis of short duration, and on the twenty-ninth day x-ray films revealed evidence of osteomyelitis near the right sacroiliac joint. A low grade fever occurred on the forty-first day of illness, but it subsided promptly after a short course of sulfathiazole treatment. When seen eighty-eight days after the onset of his illness the patient was apparently well and roentgenograms showed healing of the focus of osteomyelitis.

Summary.—A schoolboy aged 13 years with acute osteomyelitis of the ilium entered the hospital in coma resulting from severe bacteremia. Slight clinical improvement resulted from penicillin administered in the usual doses, but fever and bacteremia persisted. Only after massive doses of the drug were given over a period of twenty-four hours did the patient recover. Because the supply of penicillin became temporarily exhausted, sulfonamide therapy was later resorted to in order to prevent possible recurrence of the infection.

CASE 21.—History.—F. A., a girl aged 14 years, suffered an infection of the upper respiratory tract two weeks before admission to the hospital. Two days before entry she complained of severe left frontal headache and noted low grade fever and swelling of the left eyelid. When first seen in the hospital she appeared to be acutely ill with fever and edema of the left side of the face, including the eyelids. The nasal mucosa was swollen, and purulent discharge was draining from the nose. An x-ray film revealed opacity of the left maxillary sinus. The only other significant condition observed on admission was the presence of slightly dilated retinal veins in both fundi. The patient had received sulfathiazole before admission and was given sulfamerazine in the hospital, the blood level reaching 11.4 mg. per hundred cubic centimeters. On the fifth day of illness a small incision was made in the left upper eyelid.⁸ No pus was obtained, but culture of the serosanguineous material recovered showed hemolytic *Staphylococcus aureus*. The same organism was cultured from the nose. On the following day there was noted proptosis of the left eye with severe limitation of motion and swelling of the left eyelids (fig. 5). The right eyelids also were swollen, and although there were no demonstrable signs of meningitis and the blood was sterile on culture, a diagnosis of probable thrombophlebitis of the left cavernous sinus was made. Sulfonamide therapy was discontinued, and the patient was given penicillin, as shown in figure 5. Her condition steadily improved, and the fever fell by lysis. The patient's recovery was complete except for slight residual weakness of the left superior oblique muscle.

Summary.—A girl aged 14 years with left maxillary sinusitis complicated by staphylococcal cellulitis of the face and orbit and probably thrombophlebitis of the left cavernous sinus failed to respond to sulfonamide chemotherapy but made a rapid recovery when given penicillin.

Pneumococcal Infections.—Eighteen patients with pneumococcal infections were treated with penicillin. The results of treatment are summarized in table 2. Among the 9 patients with pneumococcal meningitis treated with penicillin there was only one death. The 1 patient who failed to recover was an infant aged 7½ months who had been suffering with meningitis for twenty days before treatment was instituted.

Six patients with pneumococcal pneumonia were treated with penicillin and 2 died. The first patient who failed to recover was a man aged 72 with pneumonia of eight days' duration. He died within twenty-four hours of the onset of treatment. The second fatality was that of a man aged 45 admitted to the hospital with uremia apparently due to sulfonamide nephritis. Death occurred after two days of treatment.

The results of penicillin treatment in 3 cases of empyema were inconclusive. The drug was injected directly into the pleural space. In 2 cases surgical drainage of the empyema was eventually deemed necessary, and in the third case, in which surgical intervention was not required, culture of the pleural fluid was

Fig. 5.—Cellulitis of face and sinusitis responds to penicillin.

sterile before penicillin treatment was begun although pneumococci had been seen in the stained sediment.

Abstracts of 2 of the cases of pneumococcal meningitis are presented:

CASE 37.—History.—T. H., a woman aged 60, became ill with pain in the right ear and a purulent aural discharge two months before she entered the hospital. These symptoms per-

8. The operation was performed by Dr. A. C. Stutsman.

sisted for one month, at the end of which time she began to complain of tinnitus and vertigo. Forty-eight hours before admission to the hospital she became acutely ill with fever, headache and finally coma. When first examined she had a temperature of 40.6 C. (105.1 F.). The right ear drum was thickened and wrinkled, and a small amount of purulent discharge was noted in the external auditory canal. The external rectus muscle of the right eye was apparently paralyzed, and there was horizontal nystagmus with the quick component to the left. The neck was stiff, and both Kernig and Brudzinski signs were positive. The leukocyte count was 36,900, and type 3 pneumococci were grown from the blood on culture. A

abscess of the petrous bone was drained. At operation the lateral sinus was examined but was not opened. Following the operation penicillin was applied directly to the operative wound at daily intervals.

The patient improved rapidly, the course being shown in figure 6. The intrathecal administration of penicillin was stopped on the ninth day. Four days later there was a recurrence of the meningitis, although the blood culture remained sterile. Intrathecal treatment with penicillin was immediately resumed, and larger doses were again employed intravenously. On the fourteenth day the operative wound was again explored and a thrombus was found in the lateral sinus, which was opened

TABLE 2.—Pneumococcic Infections

Case No.	Age	Sex	Diagnosis	Type	Blood Culture	Duration of Disease, Days	Penicillin Treatment			Body Wt., Kg.	Routes of Administration	Other Specific Treatment	Results	Comment

lumbar puncture was performed, and the spinal fluid was turbid and was obviously under increased pressure. Compression of the right jugular vein failed to cause a rise in the spinal fluid pressure. The cell count on the spinal fluid was 2,400 cells per cubic millimeter, of which 95 per cent were polymorphonuclear leukocytes. Type 3 pneumococci were identified in the fluid by the direct quellung reaction. A stained smear of the spinal fluid sediment showed approximately 8 diplococci for each leukocyte. The concentration of sugar in the cerebrospinal fluid was 8 mg. per hundred cubic centimeters. X-ray studies of the right mastoid and petrous bones (fig. 6) revealed evidence of mastoiditis and destruction of bone in the region of the petrous apex. Penicillin therapy was begun immediately by both intravenous and intrathecal routes, and on the second day of treatment a radical mastoidectomy was performed⁹ and an

and packed with penicillin. The right internal jugular vein was ligated in the neck. For several days small amounts of spinal fluid drained through the operative wound, but thereafter the patient made a rapid recovery. Penicillin was applied locally to the operative wound, which healed rapidly without evidence of infection.

Summary.—A woman aged 60 with otitis media, mastoiditis, meningitis, bacteremia and an abscess of the petrous bone, all due to the type 3 pneumococcus, responded promptly following mastoidectomy, drainage of the petrous abscess and intensive penicillin therapy. On the thirteenth day of her illness, however, there was a recurrence of the meningitis. A second operation was performed, at which the lateral sinus was opened and packed and the external jugular vein ligated in the neck. Following the second operation and further intensive penicillin therapy the patient promptly recovered.

9. By Dr. T. E. Walsh.

CASE 38—History.—R. T., a girl aged 18 years, had had frequent attacks of headache and pain in the right ear since childhood. For five years she had had intermittent otorrhea. Three weeks before she was admitted to the hospital she noticed drainage from her right ear and complained of pain in and behind the ear. Fifteen hours before her admission to the

Fig 6.—Pneumococci mastoiditis and meningitis

hospital she was seized with a severe headache and soon fainted. Although she promptly regained consciousness, the severe headache continued and she gradually became delirious. When first examined, her temperature was 39 C. (102.2 F.) and she was drowsy and difficult to arouse. There was a small amount of greenish yellow discharge from the right ear, and the right

Fig 7.—Chronic otitis media and meningitis from pneumococcus.

drum was perforated in two places and was of a dull red. Her neck was stiff, and the Kernig and Brudzinski signs were positive. There was a leukocytosis of 18,250 and a type 3 pneumococcus was cultured from the blood. The spinal fluid was cloudy and contained 1,670 polymorphonuclear leukocytes per cubic millimeter. Although no bacteria were seen on smear of the spinal fluid sediment, the type 3 pneumococcus was discovered in the fluid by culture. When second lumbar puncture

was performed twelve hours later gram positive diplococci, identified as type 3 pneumococci, could be seen in the spinal fluid and the cell count had risen to 4,700. An x-ray film of the right mastoid region showed increased density of the mastoid cells with destruction of bony trabeculae. When the patient first entered the hospital she was given sulfadiazine, but this therapy was discontinued on the second hospital day and penicillin treatment was begun. The drug was given intravenously and intrathecally, as shown in figure 7. On the fourth day of illness a simple mastoidectomy was performed¹⁰ and, although granulation tissue and friable bone were found at operation, cultures of the tissue were sterile. Following the operation the meningitis subsided rapidly, and the patient had no further difficulty.

Summary.—A girl aged 18 years who gave a history of chronic otorrhea for five years was admitted to the hospital with chronic otitis media, mastoiditis and a meningitis due to the type 3 pneumococcus. Following intensive penicillin therapy and a simple mastoidectomy she recovered promptly in spite of the fact that her illness was complicated by bacteremia.

(To be continued)

MANAGEMENT OF CHANCROID IN A TROPICAL THEATER

REPORT OF 1,555 CASES

MAJOR E. M. SATULSKY

MEDICAL CORPS, ARMY OF THE UNITED STATES

Chancroid, or ulcer molle, is an acute, inflammatory, destructive ulcer characterized by very slight induration and moderate pain on palpation. It is caused by venereal inoculation with *Hemophilus ducreyi* and occurs usually on the genitals or the surrounding skin. Other areas may also be involved, usually as a result of autoinoculation.

The causative agent was first described by Augusto Ducrey in 1889 and is found in the purulent discharge from the surface of the lesions. It is a small nonmotile, non-spore bearing, non-acid fast, gram negative bacillus measuring from 1 to 2 microns in length and about 0.5 micron in thickness. It appears as a short rod and may be arranged in pairs, groups or chains lying parallel to one another. Several other forms may be assumed including a parallel "school of fish" arrangement. It may be intracellular or extracellular in position.

Variations in staining characteristics have been described by various workers, and numerous methods have been devised for culturing the organisms. The most recent method is described by Dienst,¹ who concluded that a medium containing defibrinated rabbit blood, cystine, dextrose and beef infusion agar is best suited for the purpose and found that the bacillus grows best at 28 to 32 C., with a certain amount of moisture necessary for growth on the surface of the medium.

INCIDENCE

The Surgeon General's Reports² indicate that there were 39,044 primary admissions for chancroid in the Army in 1917-1918 and that they comprised 11 per cent of the total of the more common venereal diseases.

10. By Dr. A. C. Stutsman.

The department surgeon supplied the statistics.

Read in part before the 15th Annual Medical Society, June 20, 1944.

Captains A. Paul and William Halpern rendered valuable assistance in this study.

From the Medical Service, Section of Dermatology and Syphilology, 210th General Hospital.

1. Dienst, R. B.: New Preparation of Antigen for Intracutaneous Diagnosis of Chancroidal Infection, *Am. J. Syph., Gonorr. & Ven. Dis.* 26: 201-203 (March) 1942.

2. Chancroidal Infection, in Ireland, M. W.: *Medical Department of the United States Army in the World War*, Washington, D. C., Government Printing Office, 1928, vol. 9, chapter 7, p. 287.

Primary admission of all venereal disease patients between April 1917 and December 1919 was 86.6 per thousand annually, or 10.2 per cent of the total admissions to army hospitals.³ In the United States in 1918 the rate for enlisted troops is shown in table 1.⁴

Turner and Sternberg⁵ state that during recent months the rate of venereal infection in the Army has

TABLE 1.—Rate of Syphilis, Gonorrhea and Chancroid for Enlisted Troops in the United States in 1918

Total.....	2,240

been below peacetime levels and less than half that recorded during World War I. They also state that, among troops stationed in the United States, chancroidal lesions comprise about 6 per cent of all cases of venereal disease. An examination of the statistics in table 3 will reveal that in this area chancroid comprised 38.66 per cent of all venereal diseases in 1942 and 27.25 per cent in 1943. This disease presents a more serious problem in this area than in the zone of interior.

Greenwald,⁶ at a post in the United States where the ratio of colored soldiers to white is about 1 to 5, reports 73 colored to 3 white primary admissions during a nine month period, with a ratio of approximately 120:1. In a series of 175 patients, Kornblith and his co-workers⁷ report 127 Negroes, 44 white persons, 3 Puerto Ricans and 1 Chinese. Rauschkolb⁸ reports a 66 per cent colored incidence in civilian clinic practice.

In the Panama Canal Department, where there were relatively few colored soldiers, the high percentage of chancroidal infections in white soldiers is significant. While there is a decided variation from month to month, it is readily seen that the trend has been precipitously down since May 1943 (charts 1 and 2). The dramatic reductions in the total venereal disease rate and also in the chancroid rate are the results of a vigorous and sustained campaign waged by the medical officers of this department under the guidance and auspices of the surgeon. This campaign has stressed one thing above all others: adequate and thorough prophylaxis. That such prophylactic measures are effective for all venereal diseases, and chancroid to an even greater extent than the others, has been conclusively proved.

7. Kornblith, B. A.; Jacoby, A., and Chargin, L.: Chancroid: Treatment with Sulfathiazole and Sulfanilamide, J. A. M. A. 117:2150 (Dec. 20) 1941.

8. Rauschkolb, J. E.: Circumcision in Treatment of Chancroidal Lesions of Male Genitalia: Further Observations, Arch. Dermat. & Syph. 39:319 (Feb.) 1939.

The incidence of clinical chancroidal infection in females is much less frequent than in males. There is evidence that the Ducrey bacillus may exist in the female genitalia as a saprophyte and when transplanted to other tissues may then become a pathogen. Levin⁹ has stated that the female may act as a symptomless carrier of the disease.

This report deals with 1,555 patients in whom the diagnosis of chancroid was made (table 2). In this series an average incubation period of three to ten days elapsed between the time of sexual exposure and the onset of the ulcerations. All the patients were male soldiers in good health and physical condition. Sixty-two were colored soldiers and the remainder white and American Indian troops. In all cases there were definite penile ulcerations suggestive of chancroid. I have verified the observations of many workers who have reported an initial small reddish macule which becomes papular, then pustular and finally ulcerative as the result of maceration and friction. Several patients presented lesions involving the base of the penis and the pubis; others had lesions involving the perineal area and intergluteal aspects of the buttocks in addition to the penile lesions; 1,160 patients had multiple lesions and 390 presented single lesions. Most of the ulcers appeared at the edges of a phimotic prepuce, on the mucous membrane of the prepuce or in the coronal sulcus. The areas about the frenulum were frequently involved, with subsequent perforation or destruction of this part. Eight of the patients were circumcised and presented lesions on the frenulum and in the coronal sulcus. These are the areas apparently subjected to the greatest trauma during the sexual act.

Clinically, a chancroidal infection is manifested by the appearance of ragged, irregular, slightly indurated ulcerative lesions covered with a variable amount of yellow-gray purulent material. This pellicle wipes off easily and reveals a necrotic, dirty, granular base which bleeds easily when manipulated. The ulcers are of various sizes and shapes and as a rule are circinate

or ovoid in outline. The edges are soft, friable, slightly indurated and irregular and may be slightly undermined. A reddened inflammatory and slightly edematous areola is usually present. The ulcers spread by coalescence and peripheral extension; they are inoculable and autoinoculable. The high percentage of multiple lesions in this and other series of cases is apparently due to the autoinoculability. There is

9. Levin, E. A.: Diagnosis of Chancroid, Urol. & Cutan. Rev. 45:587 (Sept.) 1941.

usually unilateral or bilateral swelling of the inguinal lymph nodes, which may be very tender and painful on walking or on palpation. Fifty-six per cent of the patients showed this involvement. Those with advanced cases who were transported over long distances to this hospital showed fever, much discomfort and malaise. Several cases showed spontaneous rupture of inguinal nodes and others presented evidence of recent incisions for drainage. These cases all showed evidences of

Chart 1.—Graphic representation of rate per thousand annually by months of chancroid and total venereal disease.

secondary infection. In most of the cases the lymph nodes were enlarged approximately to the size of a small walnut. They were firm, elastic, movable, slightly tender on palpation, not matted and nonsuppurative. The overlying skin in these cases was normal. More advanced cases showed inflammation of the skin, matting and acute inflammation of the lymph nodes, extreme tenderness and variable degrees of softening. The lymphatic swellings in the groin which later gave rise to abscesses are commonly spoken of as "buboes."

DIAGNOSIS

The diagnosis of chancroid was made on clinical grounds alone after laboratory procedures were used to eliminate complicating diseases, particularly syphilis. A diagnosis of chancroid should not be made, despite the typical clinical picture, until primary syphilis has been ruled out. Each patient, on admission, was put to bed and warm continuous saline compresses were applied to the affected areas. A minimum of three daily dark field studies for *Treponema pallidum* were made; some cases were studied for longer periods before syphilis was differentiated from chancroid. In lesions due to both diseases the diagnosis is more difficult. Each patient with enlargement of the inguinal nodes was tested with chick embryo antigen (Frei test) before the diagnosis of chancroid was made. Serologic tests for syphilis (Wassermann and Kahn) were done on admission and at weekly intervals in two separate laboratories during the hospitalization of the patient. Because of the possibility of coexistent syphilis, all military personnel in this department with the diagnosis of chancroid have a serologic test for syphilis performed at monthly intervals for three months following discharge from hospitals.

Various laboratory procedures for the diagnosis of chancroid have been reported and advocated in the literature. These include the Ito-Reenstierna skin test and the staining or cultural isolation of the Ducrey bacillus. Several workers have stated that they consider these procedures the most reliable single factors in the precise diagnosis of chancroid.

The Ito-Reenstierna test is a reaction to Ducrey vaccine injected intradermally. The original vaccines employed killed Ducrey organisms. Cole and Levin¹⁰

described an intracutaneous test for chancroidal infection using sterilized pus from a bubo prepared like the antigen for the Frei test. Sanderson and Greenblatt¹¹ described the preparation from a culture of a vaccine for the skin test. An accepted commercial vaccine is now available. There is disagreement as to the time intervals between the appearance of the infection clinically and the response of the skin to the vaccine. Reports vary from six days to five weeks for the development of this allergic response of the skin.¹²

A positive reaction after the intradermal injection of 0.1 cc. of vaccine is supposed to mean a present or a past healed chancroidal infection. The Suttons¹³ state "It does not mean that the sore of the patient at the time of the test is certainly chancroid or is only chancroid." It has been stated, however, that a negative test dependably rules out a chancroidal infection. Some workers advocate the use of this test and report high percentages of positive results. Greenwald⁶ reports positive skin tests in three fourths of the 75 cases he observed. Kornblith⁷ states that the reaction was positive and specific in 95 per cent of his 175 cases but adds that the test is more important when the results are negative to exclude active chancroidal disease. The permanence of the skin test together with its false positives and negatives must always be kept in mind.

Some workers⁷ have stated that the identification of the Ducrey bacillus on smears stained with the Unna-Pappenheim method (methyl green pyronine) was found to be the most important single diagnostic criterion. They report the identification of the organism in 88.5 per cent of the cases in routine smears. Others, using the ordinary Gram stain, found the smears to be positive in 65 per cent of the cases.⁶

It is probable that other strains of streptococci may produce ulcerations morphologically identical with chancroidal infections. The Suttons¹⁴ stated "It is probable that some chronic destructive chancroidal lesions are actually microaerophilic streptococcal ulcers." Turner and Sternberg,⁵ in discussing chancroid infections, state that, since diagnostic methods usually available are often none too reliable, it is possible that more than one etio-

Chart 2.—Graphic representation of chancroid by months.

logic entity is being encountered. They state further that more clinical and bacteriologic studies on this problem are needed. Knott and his associates¹⁵ report

that the results of the diagnostic skin tests for chancroid should be interpreted with caution. A positive reaction does not necessarily establish the diagnosis nor a negative reaction exclude it. The best criterion in the differential diagnosis of chancroid remains the clinical appearance of the lesions. The skin reactions are at best of confirmatory value and do not alone suffice to establish a diagnosis.

The Surgeon General of the United States Army states¹⁶ that the laboratory tests for the diagnosis of chancroid (Ito-Reenstierna skin test or the staining or cultural isolation of the Ducey bacillus) are not recommended.

Pursuant to these instructions, the diagnosis of chancroid in this series was not made on laboratory findings or skin tests but was made on clinical grounds after other laboratory procedures were used to rule out other diseases or mixed infections. The diagnosis of "ulcers, penile, cause and type undetermined" was made on small, atypical superficial ulcerations which healed rapidly under saline compresses while dark field examinations were being done.

THERAPY

Sulfonamide therapy has become the therapeutic method of choice in the treatment of chancroidal infections. Before its advent various local and systemic measures were advocated and used. These included various types of local applications, the administration of foreign proteins, vaccines, arsenicals, roentgen rays and many other forms of therapy. Local surgical procedures and cauterizations with electrical and chemical means were employed for many years. The sulfonamides have greatly reduced the duration of the disease, complications have been avoided and tissue destruction with extensive scarring have been reduced to a minimum. Circumcisions and other operative procedures are strictly avoided during the acute phases of the disease and have not been found necessary or advisable in this series. During surgical manipulations the infection may be transmitted by means of dressings, towels and instruments. Rauschkolb⁸ found autoinoculations along the lines of incision in a series of 247 patients treated routinely with circumcision. After an adequate trial of therapy, a dorsal slit was necessary in 6 of our patients because of severe phimosis which interfered with proper drainage and therapy. We agree with those workers who state⁷ that "circumcision after a cure of a chancroidal infection should be deferred for at least two or three months after all signs of local infection have completely subsided. The risk of poor healing or reactivation of sluggish organisms in the depths of the tissues if operation is performed earlier is always present."

In cases with soft, fluctuant, suppurative inguinal glands incisions and drainages were not performed. The affected areas were cleaned thoroughly with warm water and soap and painted with 3.5 per cent tincture of iodine and alcohol. A small cannula was inserted firmly into the point of maximum softening. In some cases ethyl chloride was used as a spray for local anesthesia. The pus was aspirated with a syringe through the cannula, aided with slight manual pressure when necessary. After all the pus was evacuated, 1 to 1.5 cc. of 7 per cent tincture of iodine was instilled into

the cavity through the cannula left in situ. This caused a moderate degree of temporary burning in some patients, while others tolerated it without complaints. A pressure bandage was applied following removal of the cannula and the patient kept at bed rest for the following three to four days. During this time there is drainage of an iodine stained semipurulent serum and clumps of purulent material through the small opening in the skin. With the removal of the infected material the pain and discomfort of the patient cease almost immediately and the fever begins to subside. In five to seven days the area is completely healed without any sequelae.

Many types of local medications were used in attempting to discover the most efficacious combination of drugs to instil into the gland cavity. These included insufflation of various sulfonamide powders, sulfonamide powders in glycerin, thymol iodide powder, iodoform powder, solutions of thymol iodide and iodoform, azochloramide in triacetin 1:500 and balsam of Peru. The instillation of 7 per cent tincture of iodine has given us excellent results in all cases in which it was employed.

It has been our practice to avoid local and systemic therapy while the dark field examinations are being done. We have found that warm saline compresses if adequately applied are sufficient to clean local lesions prior to dark field study. After syphilis has been ruled out by a sufficient number of negative examinations, local therapy is instituted. This consists of thorough washing with warm water and white soap twice a day and careful drying of the affected parts. Powdered sulfanilamide is dusted on liberally and a loose dressing applied. This is repeated twice daily until the lesions heal. In patients with a tight phimosis and underlying ulcerative lesions, the phimotic preputial cavity is irrigated twice daily with a small hand syringe using a warm 1:5,000 potassium permanganate solution. In small superficial chancroidal lesions local therapy alone may suffice. Where indicated clinically oral sulfonamide therapy is employed simultaneously. For larger, burrowing, deep and secondarily infected ulcerations systemic administration of sulfonamides by mouth was necessary immediately.

Oral systemic therapy consisted of sulfathiazole 1 Gm. (15 grains) four times a day for five days followed by 0.5 Gm. (7½ grains) four times a day for ten days. This is a total intake of 40 Gm. (600 grains) in fifteen days. In attempting to determine the most efficient regimen of therapy, other sulfonamides were used. Sulfanilamide may be used in doses of 1 Gm. (15 grains) three times a day for five days followed by 0.6 Gm. (10 grains) four times a day for ten days. Sulfadiazine was used in doses of 1 Gm. (15 grains) four times a day for five days followed by 0.5 Gm. (7½ grains) four times a day for ten days. The latter drug was discontinued, because at the time this study was made cases of anuria were reported in the literature following its use and several cases occurred in this hospital. There were no complications from the concomitant use of local and systemic sulfonamide therapy. There were no major toxic reactions to the oral administration of the various sulfonamides. Some patients had nausea, vomiting and mild attacks of dizziness. Cyanosis of the lips and finger nail beds was noted in a few instances. Dermatitis medicamentosa manifested by urticarial, erythematous and scarlatiniform eruptions

16. Diagnosis and Treatment of the Venereal Diseases, Circular Letter No. 74, July 25, 1942, paragraph 5.

and by erythema nodosum lesions was also found. Each patient was carefully observed daily for untoward symptoms or signs of toxicity. Toxic reactions were found more commonly with sulfanilamide than with sulfathiazole. There were no cases of anuria, hematuria or dysuria. In 22 cases these drugs were discontinued by mouth because of persistent nausea, vomiting or a sudden decrease in the white blood cell counts. In 10 additional cases with gastrointestinal upsets the drugs were tolerated without complaint when administered with sodium bicarbonate 10 grains (0.6 Gm.) with each dose. Fluids were forced on all patients receiving oral sulfonamide therapy. Blood counts and urinalyses were done on admission. At three day intervals checks were made on the hemoglobin, white blood cell count and the urine of each patient. Sulfonamide blood levels were not determined.

All lesions healed under the therapy outlined without surgical intervention. Superficial infections healed with local applications of sulfanilamide powder only. Patients were discharged from the hospital to full duty when all lesions were completely healed and epithelized. Small inguinal glands were absorbed and responded well to systemic therapy with sulfonamides, bed rest and ice caps locally.

The average hospitalization of all lesions in this series was 11.2 days. In 1918 the average time lost from duty was 24.9 days.²

There were 55 patients who developed subsequent penile lesions and were readmitted to the hospital:

A. Eighteen of these patients presented new lesions which were positive for *Treponema pallidum* on reexaminations.

B. Thirty-seven patients presented clinical lesions of chancroid.

(a) Nine patients have histories of sexual exposures without mechanical or chemical prophylaxis within sixty days despite rigid quarantine.

(b) Twenty patients had presented small superficial lesions on the first admission and had received only local therapy.

(c) Eight patients had received local and oral sulfonamide therapy on the first admission but presented chancroidal ulcerations in the original sites and in new areas on readmission.

All these new lesions developed from three to five days after discharge from the hospital to full duty. All patients who were readmitted responded satisfactorily without reactions to further local and systemic sulfonamide therapy.

SUMMARY AND CONCLUSIONS

1. A series of 1,555 consecutive patients with chancroidal infections were treated in an army hospital.

2. All cases in which the clinical diagnosis of chancroid was made responded to local and systemic therapy with a sulfonamide.

3. An efficient method of treatment of inguinal abscesses was developed.

4. Sulfathiazole was found to be the most efficacious drug to be administered orally.

5. The average hospitalization of all cases was 11.2 days.

6. Further clinical and bacteriologic work for the more precise diagnosis of chancroid is necessary.

THE TREATMENT OF PNEUMOCOCCIC MENINGITIS WITH PENICILLIN

LEWIS K. SWEET, M.D.

Pneumococcic meningitis remains as one of the acute infections most difficult to treat successfully. Before the introduction of the sulfonamides it was almost invariably fatal. Even with the very vigorous use of sulfonamides and type specific serums the results have been far from satisfactory. The case fatality rate has been reported to vary from 58 per cent¹ to 80 or 90 per cent,² depending on the type of case received in the institution in which the study was made. Since pneumococci are highly sensitive to small amounts of penicillin, and since this agent is very effective in pneumococcic pneumonia,³ much can be expected from its employment in pneumococcic meningitis.²

Our purpose in the present report is to detail our experience with the use of penicillin in the treatment of 16 patients with pneumococcic meningitis and to compare the results with those obtained in 40 consecutive patients treated with sulfadiazine or sulfamerazine.

The 56 patients under consideration were treated by us in the wards of the Gallinger Municipal Hospital or in the private practice of one of us between July 1, 1942 and Aug. 1, 1944. Forty patients were treated up to Dec. 20, 1943 with either sulfadiazine or sulfamerazine, with the addition of type specific antipneumococcic serum in 21 cases. The sulfonamide was started immediately after the spinal fluid obtained at the initial puncture had demonstrated the presence of the purulent meningitis or, in a number of instances, when the patient was admitted for the treatment of pneumonia before there was evidence of meningitis. The serum was given intravenously as soon as the type was known. In 13 of the patients the serum was given immediately because organisms could be typed directly from the initial spinal fluid. In 8 additional patients serum was given later after typing was completed or when the specific type of serum was obtained. The dose of serum varied from 65,000 to 825,000 units, with 15 of the 21 patients who were given serum receiving between 300,000 and 600,000 units.

Since Dec. 20, 1943, when penicillin became available to us, we have treated 16 patients. They received the

same basic supportive care and in addition were given the sodium salt of penicillin either with or without sulfadiazine or sulfamerazine. Two patients also received antipneumococcic serum.

These two groups of patients have been compared on the basis of the following prognostic factors: (1) the age of the patient, (2) the site of the primary lesion leading to meningitis and (3) the number of organisms found in the first spinal fluid obtained after the onset of the meningitis. As shown in table 1, these groups are strikingly similar when examined in this way. In

each group approximately two thirds of the patients were 40 years of age or over. It is well known that the prognosis is worse in these older patients.

Pneumonia was the most frequent primary lesion detected, being present in 38 per cent of the sulfonamide group and in 25 per cent of the penicillin group. Endocarditis was present in 10 and 6 per cent of the two groups respectively, and head injuries in 5 and 6 per cent. No antecedent focus was demonstrated, because the patient was too critically ill on admission to give a satisfactory history, in 18 and 31 per cent of the two groups respectively. When meningitis originates from any of these primary sites, or when the patient is too ill for the primary lesion to be discovered, the out-

look is usually very poor. In only 30 and 32 per cent of the respective groups was the meningitis primary or secondary to an otitis media or mastoiditis, with the relatively good prognosis that can be offered in such cases. Furthermore, the more organisms present in the initial specimen of spinal fluid, the poorer the prognosis. We found that in 75 per cent of each group there were a sufficiently large number of organisms in this specimen to allow immediate direct typing by the Neufeld technic. Therefore, according to all these criteria, these two groups were for the most part composed of patients whose illness was very severe and whose prognosis was poor, the general severity of the illness being as unfavorable in one group as in the other.

When we consider the results of the two types of treatment, however, there is a definite difference (table 2). Among the 40 patients treated with sulfonamides there were only 3 recoveries, whereas among the 16 patients who received penicillin there were 3 recoveries. All 3 patients who recovered under the older method of therapy had very mild cases of meningitis. They were never very toxic or completely comatose. In 1 of these patients there were sufficient organisms for Neufeld typing from the initial spinal fluid, but the pneumococci were not numerous; in 2 patients the organisms were demonstrated on culture only.

The patients who received penicillin are presented in detail in table 3. They are grouped in accordance with the concomitant treatment employed with penicillin and according to the route of administration of penicillin. The first 3 patients received penicillin both intrathecally and intramuscularly and received no sulfonamides. One patient (patient 3) recovered. This patient, a Negro woman aged 45, had severe meningitis secondary to mastoiditis. Her mastoid was drained surgically and she was given very large doses of penicillin intrathecally twice daily for a week. Her spinal fluid became sterile but a pronounced pleocytosis persisted, the dextrose level was very low, the patient's fever remained high and her general condition remained poor. Intramuscular penicillin was then started, and the patient immediately began to improve.

The second group of 5 patients (4 to 8 inclusive) received intrathecal penicillin and sulfamerazine or sulfadiazine. There were 3 recoveries in this group. The meningitis in 1 of these 3 patients was primary and in the others was secondary to pneumonia and to otitis media. Penicillin was given in doses of 10,000 to 15,000 units twice daily for from three to ten days, then daily for periods of from twelve to thirty-two days. The average blood sulfonamide level for the 3 patients was approximately 14 mg. per hundred cubic centimeters. The meningitis in these 3 patients was relatively less severe than the average of the group. Furthermore, in none of them were organisms present in adequate numbers for immediate typing. Accordingly, while it is highly improbable that all of them would have recovered on sulfonamide therapy alone, we cannot assume that the choice of therapeutic agents used in their treatment is the optimal one for all cases.

The remaining 8 patients received penicillin both intrathecally and intramuscularly and also received sulfonamides. Three patients recovered. One was a Negro woman aged 29, who had a severe meningitis without evident antecedent focus. She received intrathecal penicillin for twenty-seven days and then, after evidence of a neurologic lesion developed (which will be discussed

later) was given intramuscular penicillin for an additional seven days. As the meningitis was essentially well when the intrathecal penicillin was discontinued, this patient might be considered as another patient cured by penicillin intrathecally in combination with sulfamera-

penicillin intrathecally and intramuscularly for forty-six and forty-eight days respectively. During this time there were several periods of remission of the disease, but on each occasion a reduction of the dosage of penicillin was followed by an immediate exacerbation

zine. Two of the patients who recovered were infants. In 1 the primary lesion was a head injury. This was complicated first by a pneumonia and bacteremia, then by meningitis. In the other infant the meningitis was a primary infection. Both infants received large doses of

of the meningitis. Thereafter a combination of sulfadiazine and penicillin was used for forty-one and sixty days respectively. Both infants recovered, but not until after pronounced cerebral atrophy with resultant mental deterioration had developed. Of the other 5 patients

in this last treatment group, 4 died within twenty-four hours after the institution of treatment, and 1 died of endocarditis after his meningitis had cleared completely.

Reactions that apparently derived from the intrathecally injected penicillin have been encountered in 4 of the patients treated by this method. They have been of two types, mild sensory changes and severe sensory and motor changes. Both types of lesion have involved the lower segments of the spinal cord or the roots of the lumbosacral plexus of nerves. The mild sensory changes occurred in 2 patients, 4 and 8, and consisted of pain in the legs, and in patient 8 pain in the back also during the intrathecal administration of penicillin. The symptoms appeared on the tenth and twenty-third days after the institution of intrathecal penicillin therapy, persisted until the penicillin dosage was reduced or discontinued and then disappeared.

The severe reactions also occurred in 2 patients who had prolonged intrathecal penicillin treatment. Patient 3 developed severe pain in the legs and toes during the intrathecal administration of penicillin, beginning on the tenth day of therapy. By the seventeenth day there was urinary retention with overflow. The presence of a hypotonic bladder was verified by cystometrogram. The intrathecal penicillin was then discontinued, the symptoms began gradually to abate, and the patient was discharged completely recovered sixty-three days after entry. The other patient, 13, had a severe type 12 pneumococcal meningitis without definite primary lesion. She received penicillin intrathecally twice each day. On the tenth day she began to complain of intense pain in the legs with each intrathecal injection. On the eighteenth day lumbar punctures became impossible because of spasm of the muscles of the back. Thereafter the penicillin was given into the cisterna magna for ten more days. During this time the patient developed a hypotonic neurogenic bladder, verified by cystometrogram, and paralysis of both legs, with pronounced hyperesthesia and absent tendon reflexes. On the twenty-eighth day the intrathecal penicillin was discontinued and the drug was given intramuscularly in large doses for one week. The patient made a very gradual recovery from her neurologic lesion and was discharged one hundred and twenty-four days after entry, with almost complete recovery from her neurologic lesion.

In 1 patient, 7, an attempt was made to secure better diffusion of the intrathecal penicillin by giving it alternately into the cisterna magna and lumbar subarachnoid space. The cerebrospinal fluid became bloody after twelve days, at which time the patient became deeply comatose. The patient died on the nineteenth hospital day. Although the autopsy showed a purulent exudate over the cerebral cortex, the most significant findings were a large blood clot filling the cisterna magna and numerous puncture holes in the meninges over the medulla. There were meningeal adhesions just below the cisterna magna.

It is probable that the cerebral atrophy and mental deterioration encountered in cases 9 and 10 were due to the meningitis, but they may possibly have been due to the penicillin, since much of that drug was given directly into the lateral ventricles.

COMMENT

Few reports on the use of penicillin in the treatment of groups of patients with pneumococcal meningitis have appeared in the literature. The reports that are avail-

able⁴ tend to minimize the severity of this infection and to indicate that its treatment with this drug is relatively simple. Working in a clinic where the majority of patients with pneumococcal meningitis are 40 years of age or over and where the meningitis usually is a complication of some other serious infection, we have found that such an attitude is not and probably never will be tenable. The inherent severity of the disease is evidenced by the fact that of our 16 patients treated with penicillin 6 died within forty-eight hours after the treatment was begun. Of those patients who recovered, in only 2 were we able to discontinue treatment successfully within two weeks, and in 5 it was continued for twenty-four, thirty-two, thirty-four, eighty-seven and one hundred and eight days. In 3 of these patients and in 1 of the 3 patients who died after surviving for periods longer than two days an exacerbation of the meningitis occurred almost immediately after a premature reduction of the penicillin dosage.

This brings up a question that to us has been very perplexing: When can penicillin be discontinued with safety? At present we are unable to give a satisfactory answer. We have had patients with no fever whose spinal fluid findings were essentially within the normal range for as long as four days, who nevertheless showed an exacerbation when the dosage of the drug was reduced. Therefore we are strongly inclined to continue the drug for considerable periods after the clinical evidences of infection have subsided.

Our preference for this course, however, is tempered by the apparent reactions to intrathecal penicillin that we have seen. It is impossible from our present data to determine whether these reactions are due entirely to the action of penicillin itself, to certain impurities present along with the drug, to repeated lumbar punctures or to the meningitis. Such reactions were seen very rarely in meningococcal meningitis treated with intrathecal serum⁵ and were thought to be due to the meningitis rather than to the repeated spinal punctures. Since the initial symptoms in our patients accompanied the administration of penicillin, and since the severity of the symptoms increased in proportion to the duration of therapy after the onset of the complication, it seems probable that the reactions were due to the irritant effect of the penicillin itself or of the impurities present with it.

As a result of these severe reactions, and as a result of our difficulty in terminating penicillin therapy in 2 patients (9 and 10), we feel that in the treatment of pneumococcal meningitis the patient should be given the benefit of large doses of either sulfadiazine or sulfamerazine as well as penicillin intramuscularly or intravenously at the rate of 200,000 or more Oxford units per day, so that intrathecal penicillin therapy may be reduced to a minimum. In this way the intrathecal dosage can probably be kept as low as 10,000 to 20,000 Oxford units per day. In order to reduce the irritation further, this dose should be diluted in 20 to 30 cc. of isotonic solution of sodium chloride if it is possible to administer this much fluid intrathecally. The amount

of fluid administered, however, must always be from 5 to 15 cc. less than the amount of cerebrospinal fluid withdrawn. Finally, intrathecal penicillin should be discontinued as soon as the patient shows a continuing favorable reaction, while parathecal penicillin and sulfonamides should be continued for several days more.

SUMMARY AND CONCLUSIONS

1. Sixteen patients with pneumococcic meningitis were treated with penicillin (with or without sulfonamides) with nine deaths. Among 40 patients treated with sulfonamides and no penicillin there were thirty-seven deaths. The two groups were shown to be very similar as regards the factors which are important in evaluating the prognosis.

2. The duration of treatment with penicillin varied from twelve to one hundred and eight days in the recovered patients.

3. Two patients developed mild and 2 developed severe neurologic symptoms associated with the administration of the penicillin. All of these patients recovered before leaving the hospital.

4. It is concluded that the optimal treatment of pneumococcic meningitis should include the use of penicillin and sulfadiazine or sulfamerazine. The penicillin should be given both intrathecally and systemically.

PYELOCYSTOSTOMOSIS

REPORT OF TWO CASES

ELMER HESS, M.D.

ERIE, PA.

AND

B. W. WRIGHT, M.D.

NASHVILLE, TENN.

It is often necessary to divert the urinary stream while an obstructive lesion is corrected. This, in reality, is one of the fundamental principles of certain surgical procedures on the urinary excretory apparatus. The obstructive untreated uropathies will eventually destroy the renal parenchyma. If the obstruction can be relieved in whole or in part after a definitely increasing nephrosis is discovered, the recovery of the renal parenchyma is one of the amazing features of the convalescent period.

No matter how badly damaged the renal parenchyma may seem to be, none of these cases are necessarily hopeless, even if a single renal mass is the only renal substance that can be found. We have all seen cases in which life has been indefinitely prolonged, with normal blood chemistry balance and only infinitesimal amounts of glomerular tissue clinging to the renal capsule. Equally if not more amazing is the ability of a nephrotic kidney to assume normalcy, or near normalcy, after the complete relief of obstruction. Often, however, the condition of the patient does not warrant an immediate attack on the obstruction itself. It is therefore expedient to short-circuit the urine until recovery of the renal function assures some chance for success. Temporary procedures to bring the urine to the surface of the body have been devised and used by all of us. Occasionally certain conditions arise in which obstructions above the bladder may be relieved by such a short-circuiting within the body. This should

be preferable. In these situations anomalous organs must be handled with discretion, and this is more important when the patient has only a single renal mass, whether this mass is a solitary, a fused or a horseshoe kidney.

In these cases the very life of the patient depends on the diagnostic ability, skill, experience and ingenuity of the urologic surgeon. If a surgical procedure can be planned that would temporarily sidetrack the urinary stream within the body, bypassing the obstruction, then one operation might suffice and the renal function might be indefinitely prolonged.

Many successful attempts to reimplant ureters into the bladder have been reported, but only 2 cases are now on record in which the hydronephrotic renal pelvis has been successfully anastomosed directly to the urinary bladder to bypass permanently a ureteral obstruction. The first time this operation was performed it was a "must" at the operating table. Necessity in this case proved to be the mother of invention. The second case was deliberately planned and successfully executed and these 2 cases, we believe, are unique in the annals of urologic surgery. The operations about to be described open a new avenue of approach to the treatment of certain types of nephrosis.

In 1929 one of us reported a very unusual experience. Faced with a huge hydronephrosis in the left half of a horseshoe kidney which could not be relieved by cystoscopy, an operation was created at the operating table which was designated pyelocystostomosis. The successful relief of the condition was completely reported before the meeting of the American Urological Association in 1929. Herewith are appended the drawings of the technic of this particular procedure and the x-ray examination, postoperatively, showing the patient's fistula between the pelvis of the kidney and the posterior fundal wall of the bladder.

At the time of operation this patient was 9 years of age. He was discharged from the hospital with a most satisfactory clinical result. Fourteen years later, in 1943, the patient, now an adult, was examined by the draft board and told the draft surgeon such a fantastic story that he was sent back to the clinic for confirmation and advice.

Prior to his operation in 1929 the boy had not been too bright but since operation had improved immeasurably, mentally, and had completed his required school work and was now employed in a defense plant. His story was that he had been in good health ever since and had developed as any normal boy. At the time of his examination he was perfectly well, with normal urinary output and control and had no symptoms. He did refuse cystoscopy and so check-up pyelograms are not available. His argument was Why go through a very disagreeable examination when he was in perfect health? Here, then, is a man who has lived for fourteen years following a procedure that, to the best of our knowledge, had never previously been done.

In 1943 a second case in which a similar situation existed, except that the kidney was a solitary one, came under the care of the co-author of this paper.

The patient, aged 42, was married and the father of 1 child. A diagnosis of hydronephrosis in a congenital ectopic solitary kidney was made. The condition was relieved the first time by ureteral catheterization. Three weeks later the patient again had an acute hydronephrosis and 6 ounces of urine was drained out of this hydronephrotic pelvis, with complete relief of symptoms. Thirteen days after this second admission a third

attack of hydronephrosis was accompanied by severe colicky pain in the lower part of the abdomen and suppression of urine. The nonprotein nitrogen was 106.0 and the creatinine was 7.2 mg. per hundred cubic centimeters of blood. His blood pressure had risen to 210/110 as compared to 132/94 when he was first admitted to the hospital. He had a severe headache, visual disturbances, vertigo, mental dulness and hiccups, with an obviously pending uremia. Again, cystoscopic ureteral catheterization relieved the hydronephrosis, but on August 16 it was decided to short-circuit the urine

The posterior parietal peritoneum was incised in the midline and stripped from the kidney and the posterior wall of the bladder. The lower border of the renal pelvis was first attached to the lower part of the posterior wall of the bladder by several interrupted sutures of catgut, the purpose being to protect the anastomosis from undue tension. An extraperitoneal, suprapubic cystostomy was then done, through which the finger was introduced for guidance. Corresponding vertical incisions, each 3.5 cm. long, were made in the bladder and the renal pelvis, and these were sutured together

with catgut in the same manner as is employed in a gastrojejunostomy. This produced a communication between the bladder cavity and the interior of the renal pelvis through which the index finger could be easily passed without constriction. The posterior parietal peritoneum was sutured over the united kidney and bladder and the abdominal cavity was then closed without drainage. A Pezzer catheter was sutured in the cystostomy opening with a pursestring of catgut and provided extraperitoneal drainage of the bladder. The wound in the abdominal wall was closed in the usual manner.

The patient made an uneventful recovery, and the wound healed by first intention. The only difference between this operative procedure and the first anastomosis that was done was the drainage of the cystostomy with a Pezzer catheter (in the first case drainage was effected by catheter through the urethra, and the bladder wall was closed by suture). Normal urination was reestablished on the twentieth postoperative day, and the patient was discharged on the twenty-fourth postoperative day with a blood pressure of 116/70.

Four months after his operation the patient resumed his occupation and felt well. His blood pressure had increased to 155/115. One month later examination revealed many pus cells and a heavy trace of albumin in the urine, with a slight rise of afternoon temperature.

At that time cystoscopy showed the stoma to be open, and through it a No. 5 catheter was passed into the kidney and the pelvis was lavaged with 1:5,000 silver nitrate solution. Daily irrigations of the

bladder and kidney through a soft rubber catheter in the urethra, using a silver solution, rendered the urine practically pus free after a week, but the urine continued to show some red blood cells and a trace of albumin. A cystogram at this time showed a definite diminution in the size of the kidney pelvis. The blood pressure was 130/90. The blood nonprotein nitrogen was 50 mg. and the creatinine 3.5 mg. The patient left for his home in a neighboring city, feeling quite well and ready for work.

This patient's nitrogen retention remains higher than normal but it is apparently fixed, as there has been

Fig. 1.—1. Bladder and hydronephrosis exposed through a midline incision. 2. Line of incision in the posterior wall of the bladder and the incision in the pelvis. 3. Relationship of the incision in the posterior wall of the bladder and the nephrotic pelvis. 4. Method of anastomosing the pelvis to the bladder.

by attempting to anastomose the hydronephrotic sac directly to the urinary bladder. The ectopic kidney could be seen and felt beneath the posterior peritoneum, in front of the first portion of the sacrum. A careful search failed to reveal another kidney or a missing testicle. The right ureter was a blind pouch; the left ureter entered the hydronephrotic pelvis on its upper left anterior surface and was sharply angulated at the ureteropelvic junction. The long axis of the kidney was horizontal. The blood supply to the kidney was typical of that seen in ectopias and came from the abdominal aorta.

no appreciable change in the past four months. His future is apparently dependent on how well his urinary infection is controlled and whether or not the low grade pyelonephritis is progressive. At present he seems to owe his life to the pyelocystostomy.

COMMENT

It is perfectly feasible, under certain clinical and anatomic conditions, to plan deliberately and execute the direct anastomosis of the renal pelvis and the urinary bladder. If the proper indications are the directive, the operative procedure should be a success and a secondary operation to relieve the obstruction unnecessary. The advantages when such a procedure is practical are obvious, as the drainage of the kidney is within the body to the natural receptacle for the urine and immediately does away with all of the discomforts incident to urinary drainage to the body surface.

The indications for the operation are limited, but it is definitely indicated in large hydronephroses which cannot be relieved by ureteral catheterization and where for one reason or another the remaining renal parenchyma must be preserved. The size and position of the hydronephrotic organ must be such as to make the attempt at anastomosis feasible.

A single pelvic kidney acutely obstructed, a horseshoe kidney one side of which is acutely obstructed, or a single kidney with a huge nephrosis may be handled in this manner and the result will be far more acceptable to the patient than a nephrostomy which is drained through the loin. However, if the nephrotic sac isn't large enough to be easily anastomosed, the nephrostomy will be a far better surgical approach. Then there may be

Fig. 2—Cystopneumogram showing the anastomosis between the bladder and the pelvis of the kidney; anteroposterior view, postoperatively.

several other combinations of conditions that may arise that would make an operation of this kind feasible, even though a normal kidney might be on the opposite side. In each of these cases reported there is a slight difference in operative technic, but in the main they are the same.

Drawings of the technic of both operations are presented for comparison, and we hope that this report of our experiences will stimulate others who, from time to time, are faced with such a problem to attack the situation fearlessly and with full hope of surgical success. In these 2 cases there is demonstrated a new

Fig. 3—Cystopneumogram showing the anastomosis between the kidney and the bladder, lateral view, postoperatively.

surgical operation. True, its indications are limited; but its value as a life saving procedure has been twice demonstrated. The operation is presented for your consideration as an additional weapon in our struggle to relieve distress and prolong life.

8 East Twelfth Street.

ABSTRACT OF DISCUSSION

DR. EDGAR BURNS, New Orleans: Since drainage is usually defective in such cases, one would expect hydronephrosis to be a frequent lesion. In the records at Charity Hospital in New Orleans I found 12 cases of ectopic kidneys. Two of these patients had dilated renal pelvises. The 2 cases reported by Drs. Hess and Wright certainly presented unusual problems. Obviously in the performance of the type of operative procedure they have outlined the principles of plastic surgery must be rigidly adhered to; perhaps the most important of these is freedom from tension. In order to insure adequate drainage it seems desirable to make the anastomosis as large as the size of the renal pelvis and its proximity to the bladder will permit. Otherwise the same situation might develop as is found in a diverticulum of the bladder the opening of which is too small to permit complete emptying. Although these 2 patients were men, the same situation might be encountered in women. The relationship of the uterus to the bladder and the usual site of an ectopic kidney would probably make it more difficult to accomplish the anastomosis in such cases. Even if the anastomosis could be made, the possibility of subsequent disease of the uterus would create a hazard that might prove disastrous in later years. How should the uterus be handled in such cases? From a study of Dr. Hess's case it is apparent that

the normal variations in intravesical pressure have had no influence on renal function, but I should like some comment on that point. Another point is that of obstruction to the urinary outlet. Unquestionably, back pressure would lead to more rapid destruction of renal function than is encountered when the kidneys are in the normal position. This applies especially to men who are liable to develop prostatic hypertrophy. Dr. Wright's patient is approaching that age.

DR. B. W. WRIGHT, Nashville, Tenn.: This patient is intelligent and cooperative, and I have examined him by cystoscope a number of times since the anastomosis was made. The stoma is perfectly visible and patent. It looks like the opening of a diverticulum. I have on several occasions passed a catheter transvesically through the stoma and into the renal pelvis and lavaged it. When this patient's bladder is irrigated through a urethral catheter he is conscious of and easily identifies the sensation of a distended kidney. For the first few months after he was up and about I taught him to manipulate his renal pelvis in the Credé manner, and he found that he could void, and then by pressing on his abdomen he would be able to pass some more urine, which undoubtedly was that retained in his renal pelvis. Now he is no longer able to get this second voiding, and I think it is consistent with the contracture of the pelvis. The obstruction in his case was due to the high implantation and sharp angulation of the ureter and at the operation, when we had two catheters in the ureter and filled the kidney pelvis, it seemed that the more we distended the pelvis the more acute and complete was the obstruction. Just what additional complications and problems will arise if he develops an obstruction at his bladder neck or distal thereto remain to be seen.

PENICILLIN THERAPY IN RAT BITE FEVER

W. A. ALTEMEIER, M.D.

HARRY SNYDER, M.D.

AND

GERTRUDE HOWE, M.D.

CINCINNATI

Rat bite fever is a peculiar and relatively rare disease of man which occasionally develops after the bite of a rat. There is some evidence that this condition has been known in India for two thousand three hundred years and that India may have been its source. Modern medical literature on this subject began with the report of Wilcox in 1840, who recorded a group of symptoms that followed the bite of a rat. Since then case reports have been published in nearly all of the countries of the world, including Asia, Japan, Europe, England, North and South America, Hawaii and Australia. In the United States the disease has now been reported in twenty-eight states and the District of Columbia, but the incidence has been greatest in Ohio, Pennsylvania, New York and Illinois. In spite of its worldwide distribution, an epidemic spread of rat bite fever has never been recorded. It is primarily an invasive wound infection, and this explains its sporadic occurrence.

The wild rat is the chief animal vector, and more rarely the dog, cat, pig, mouse, laboratory white rat and weasel may be the source of infection. Evidence is lacking that the flea or any other insect is concerned in transmission of the infection.

There are at least two distinct types of rat bite fever: (1) "sodoku," shown by Futaki and others to be caused by *Spirillum minus* (or *Spirocheta morsus muris*), and (2) septicemia produced by *Streptobacillus*

moniliformis, otherwise known as *Haverhillia multi-formis* or *Streptothrix muris ratti*.

Sodoku is the endemic Japanese or Oriental form, and cases of this type have been much more prevalent than the streptobacillary type seen in the United States. In fact, we have found reports of only 17 proved cases of rat bite fever produced by *Streptobacillus moniliformis*.

Fig. 1.—Course in case of rat bite fever due to *Streptobacillus moniliformis*; incubation period, ten days; rash, first six days; local inflammation absent; lymphangitis and adenitis (local) absent; arthritis absent; Kahn reaction negative.

Although it might be expected that the clinical picture would vary according to the etiologic agent, such a clinical differentiation has not been clearly established. The similarities between the two types of rat bite fever have led to their being considered variants of the same disease, and this has led to much confusion. In 1940 Allbritten, Sheely and Jeffers¹ reviewed the accessible literature and indicated certain features that tended to differentiate the spirillar from the streptobacillary form. We have summarized the essential features of the two types in table 2, using data obtained from reported cases and our own experience.

Although it has been shown repeatedly that the spirillar form responds very well to arsenical therapy, particularly with neoarsphenamine and sulfarsphenamine, no satisfactory chemotherapeutic agent has been found for the streptobacillary type. The arsenical compounds have been helpful in some cases and of no value in others. Sulfonamide therapy has also been ineffective.

During the summer of 1943 we had the unusual opportunity of treating with penicillin 3 cases of rat

Fig. 2.—Course in case of rat bite fever due to *Streptobacillus moniliformis*; incubation period, one day; rash slight on third and fourth days; local inflammation mild; local lymphangitis and adenitis mild; history of lymphangitis; arthritis absent; Kahn reaction negative; complication, gastroenteritis.

bite fever produced by *Streptobacillus moniliformis*, and the case reports are recorded:

CASE 1.—A. M., a white girl aged 10 months, admitted to the Children's Hospital on July 1, 1943, two weeks previously had been bitten by a large brown rat on the left hand

From the Department of Surgery, University of Cincinnati, and the Department of Pediatrics of the Children's Hospital. The work described in this paper was done under a contract recommended by the Committee on Medical Research between the Office of Scientific Research and Development and the University of Cincinnati.

1. Allbritten, F. F., Sheely, R. F., and Jeffers, W. A.: *Haverhillia multi-formis*, Its Etiologic and Clinical Relationship to Rat Bite Fevers, J. A. M. A. 114: 2360 (June 15) 1940.

and right foot. Within ten days she developed high fever and a cutaneous rash, which began on the face and spread rapidly over the body and extremities. At the time of admission she was acutely ill and her temperature was 103.6 F. by rectum. A fine red maculopapular rash was distributed generally over the body, including the palms of the hands and soles of the feet. The tooth marks on the hand and foot did not appear inflamed, and there was no regional lymphangitis or lymphadenitis. A mild generalized lymphadenopathy was present, however.

The white blood cell count was 17,500 per cubic millimeter with 62 per cent polymorphonuclears and 38 per cent lymphocytes. The Kahn test and urinalysis were negative.

During the first twenty-four hour period of hospitalization a total of 1 Gm. of sulfathiazole was administered. At this time the blood culture taken on admission was reported positive for *Streptobacillus moniliformis*. Sulfathiazole therapy was discontinued, and treatment with penicillin was started. At intervals of four hours 12,500 units of sodium penicillin was given intravenously for two and one-half days. For six days thereafter smaller doses of 5,000 units were given intramuscularly, a total of 302,500 units being administered in the eight and one-half days. Twenty-four hours after the onset of penicillin therapy

12,500 units of sodium penicillin every four hours intravenously or intramuscularly the first forty-eight hours. Treatment was continued for four and one-half days, a total of 212,500 units being given (fig. 2).

All blood cultures after the start of penicillin therapy were negative, while all before had been positive. The rash disappeared within twenty-four hours, and the temperature fell gradually during the following three days. The temperature

Fig. 3.—Course in case of rat bite fever due to *Streptobacillus moniliformis*: incubation period, three days, local inflammation slight, regional lymphangitis questionable; Kahn reaction negative.

TABLE 1.—Essential Features of Spirillar and Streptobacillary Types of Rat Bite Fever

	Spirillar	Streptobacillary
1. Common geographic location	Orient, Europe	America, Europe
2. Incubation period..	1-3 weeks	1-3 days usually
3. Bite wound	Exacerbation with development of local swelling, pain and purplish red discoloration 1-3 weeks after bite; chancre like ulcer develops	Usually heals readily
4. Cutaneous rash	Usually distinct; large macular or papular, never petechial	Fine maculopapular, morbilliform or petechial; may involve skin of palms (fig. 4)
5. Arthritis ..	Usually absent	Commonly present
6. Regional lymphangitis and lymphadenitis	Present	May be present
7. Blood cultures	Negative	Positive for <i>Streptobacillus moniliformis</i>
8. Wassermann reaction	Usually negative	Negative
9. Kahn reaction	Tends to become positive at end of fourth week	Negative
10. Polymorphonuclear leukocytosis	Present	Present
11. Secondary anemia	Present	Present
12. Arsenotherapy ..	Prompt response	Little or no response
13. Sulfonamide therapy	No data	Little or no response

the blood culture was negative and remained so. At the same time the temperature fell sharply, the rash disappeared and the child made a rapid recovery without evidence of relapse, complication or sequela. She was discharged on July 29, 1943 and has had no recurrence (fig. 1).

CASE 2.—R. F., a white boy aged 2 months, was admitted to the Children's Hospital on Aug. 2, 1943 with a history of having been bitten by a large brown rat in several places about the right ankle. Twenty-four hours after the bite he developed high fever and a "red streak" on the injured leg.

On admission the infant appeared acutely ill and had a temperature of 103 F. by rectum. There were tooth marks on the right foot and ankle and a mild inflammatory reaction about them. Regional lymphangitis was present, but the inguinal glands were not enlarged or tender. No rash was present at first, but a few macules were seen on the feet the day following admission.

The white blood cell count was 13,400 per cubic centimeter with 71 per cent polymorphonuclears. The urinalysis and Kahn tests were negative.

Blood cultures taken on the day of admission and the two days following were positive for *Streptobacillus moniliformis*. Penicillin therapy was started on the third hospital day with

response may have been influenced in part by the development of diarrhea, which seemed to have no relation to the therapy. The infant suffered no relapse and was discharged well on August 21. Follow-up observations have shown that he has had no recurrence.

CASE 3.—J. T., a white girl aged 4½ years, was admitted to the Cincinnati General Hospital on Aug. 13, 1943 with a history of having been bitten on the left hand by a rat seven days previously. Three days after the bite she developed chills and a fever of 102 F. One day later she developed a rash, and two days later she complained of pain in the hands, wrists, ankles and knees.

The temperature at the time of admission was 103 F. and the child appeared acutely ill, irritable and in pain. There was a fine maculopapular rash covering all the extremities and the face (fig. 4). There was swelling about the left hand and wrist but no evidence of inflammation about the tooth marks. A loud systolic murmur was audible over the precordium.

A white blood cell count was 9,200 per cubic millimeter and the urinalysis, Kahn and Weil-Felix tests, tuberculin test, electrocardiogram and teleoroentgenogram of the heart were all normal.

Blood cultures were positive for *Streptobacillus moniliformis* on the first day after admission, and penicillin therapy was started with 4,000 units intravenously every four hours for three days and then intramuscularly for two more days. Unfortu-

nately a total of only 132,000 units was available for treatment of this case. As in the previous 2 cases, the blood stream was promptly sterilized, but the rash and arthritis subsided in two and five days respectively. However, four days after the penicillin was discontinued the child suffered a relapse with recurrence of fever, rash and positive blood culture (fig. 3). This episode subsided spontaneously, and the child remained apparently well except for the development of furuncles on the left arm, which were apparently unrelated to the disease. Although the child seemed well, a blood culture was found to be positive

after ten days' incubation just before her discharge from the hospital. Subsequent examinations have shown that the child has remained well and the blood cultures have continued to be negative.

The *Streptobacillus moniliformis* isolated in each of the 3 cases was definitely susceptible in vitro to the bacteriostatic action of penicillin. The strain isolated from the first case was completely inhibited by concentrations of 0.05 unit of sodium penicillin per cubic centimeter of broth medium. The other two strains showed partial inhibition by 0.05 unit per cubic centimeter and complete inhibition by 0.10 unit per cubic centimeter (table 2).

to infants of 10 months and 2 months respectively. It would seem more practical to give 10,000 or 15,000 units every three hours for at least seven days in any future cases of rat bite fever treated with penicillin.

There is some tendency for this disease to clear up spontaneously after a varying number of relapses, and this feature makes the evaluation of therapeutic results especially difficult in such a small series of cases. In table 3 we have summarized the salient features of all reported cases of rat bite fever in the United States in which the diagnosis was made by recovery of *Streptobacillus moniliformis* from the blood or joint fluid. In all there have been 17 cases up to and including 1943,

COMMENT

The first 2 cases of streptobacillary rat bite fever showed a prompt and dramatic response followed by complete recovery when small doses of penicillin were administered. Definite improvement in the general condition was associated with fall in the temperature and white blood cell count, disappearance of the cutaneous rash and sterilization of the blood stream within twenty-four hours. In the third case a similarly prompt but less complete response was obtained, but a relapse occurred after discontinuance of the penicillin therapy. Because of the temporary exhaustion of our supply of penicillin, a total of only 132,000 units was administered to a child of 4½ years. In the light of later experiences in chemotherapy with penicillin, this unquestionably was an inadequate amount. In the first 2 cases a total of 302,500 and 212,500 units was administered

although there have been many more in which a diagnosis was made on a clinical basis only. Two of the 17 patients died as a result of their disease, and 3 more were left with persistent arthritis lasting fifty-three days in case 2, eight months in case 9 and over two years in case 14. Experience has been similar in Haverhill fever, a disease caused by the same organism without the bite of a rat or other animal. It is also evident that the duration of fever varied from thirteen days in case 8 to over four months in case 5. From this evidence it would seem that the usual case of streptobacillary rat bite fever treated by agents other than penicillin remains febrile either continuously or intermittently for a period of three to eight weeks.

Comparing the case records of the previous 17 cases with those of our 3 cases treated with penicillin, we believe that there is definite evidence that penicillin i-

effective in the therapy of this disease in that it promptly sterilizes the blood stream, shortens the course of the disease and tends to prevent the crippling effects of persistent arthritis. This clinical impression is supported by the demonstration in vitro of the susceptibility to penicillin of the three strains of *Streptobacillus moniliformis* isolated. It is suggested that penicillin may be of value in the therapy of Haverhill fever, since this disease is apparently caused by the same organism.

SUMMARY

1. There are at least two forms of rat bite fever, one caused by *Spirillum minus* and the other by *Streptobacillus moniliformis*.

2. The type caused by *Spirillum minus* responds well to arsenical therapy, but no satisfactory chemotherapeutic agent has been available for the type produced by *Streptobacillus moniliformis*.

Fig 4—Tooth marks produced by the bite of a rat and the fine maculopapular rash of the skin of the foot, including the solar aspect (case 3).

3. A review of the literature reveals only 17 cases of rat bite fever due to *Streptobacillus moniliformis* in the United States in which the diagnosis was verified by recovery of the organism. Three more cases were treated for the first time with penicillin. The therapeutic response was prompt and permanent in the first 2 cases. In the third a relapse occurred after the administration of an inadequate amount of penicillin.

4. Studies in vitro indicated that penicillin has a powerful bacteriostatic effect on the three strains of *Streptobacillus moniliformis* recovered.

5. A comparison of the course of our cases with those previously reported gives the impression that penicillin is an effective chemotherapeutic agent which shortens decidedly the course of the disease.

6. In the future, treatment with penicillin is recommended in the therapy of rat bite and Haverhill fevers.

METABOLIC STUDIES IN PATIENTS
WITH CANCER OF THE GASTRO-
INTESTINAL TRACTXIX. THE ANEMIA OF PATIENTS WITH
GASTRIC CARCINOMA

ABRAHAM OPPENHEIM, M.D.

GEORGE T. PACK, M.D.

AND

C. P. RHOADS, M.D.

NEW YORK

It is common clinical experience that patients with gastric carcinoma sooner or later develop anemia. The nature of this anemia, however, is not uniform, and variations from the macrocytic hyperchromic to the microcytic hypochromic disorders have been described. Indeed, it is not unusual to find that even in the same person the anemia may change its characteristics from month to month.

It is, of course, obvious that the existence of anemia preoperatively in these patients adds to the hazards of their operative and postoperative periods. There now is good evidence that anemia in patients submitted to prolonged surgical procedures may increase their tendency to shock states¹ and their susceptibility to infections, aggravate their usual hypoproteinemia,² impair wound healing and induce wound disruption.³ Although it is possible to repair this anemic state preoperatively by whole blood transfusions, this is only a transitory measure and its frequent repetition is not always feasible. It has been found in this hospital that the administration of whole blood to these patients induces a high incidence of febrile reactions and intravascular lysis, so that in some cases after the transfusion the blood count actually has fallen.⁴ Moreover, mere replacement therapy is not directed at the primary cause of the anemia and may mask a progressive disorder.

For these reasons it appeared to be desirable to study the nature and probable etiologic factors of the anemias in patients with adenocarcinoma of the stomach. The results of that investigation form the subject of the present communication.

METHODS

1. Hemoglobin concentrations were measured by the Sahli technic;⁵ 13.8 Gm. per hundred cubic centimeters of blood was arbitrarily set at 100 per cent. Blood counts were made in the usual manner. Anemia was considered to exist when the hemoglobin value was less than 80 per cent or the red cell count below 4.0 million per cubic millimeter. The normal color index was taken as from 0.9 to 1.1.

5. Todd, J. C., and Sanford, A. H.: Clinical Diagnosis by Laboratory Methods, Philadelphia, W. B. Saunders Company, 1943, vol. 10, p. 216

2. Marrow counts were made by the technic of Rhoads and Castle;⁶ the slides were stained with Jenner-Giemsa dye.

3. Mean erythrocyte volumes were ascertained by the method of Musser and Wintrobe.⁷ The normal range was considered to be from 80 to 94 cubic microns.

4. Urobilinogen was measured in the stools and urine as described by Watson.⁸ Total excretions greater than 200 mg. per day indicate an increased rate of intravascular lysis.

5. The existence of gastric free hydrochloric acid was ascertained in the manner of Gompertz and Cohen;⁹ 1 mg. of histamine phosphate was injected subcutaneously to stimulate acid secretion.

6. Blood loss at operation was measured by a method developed in this hospital.¹⁰

7. The fecal and urinary nitrogen and serum albumin and globulin were determined by a Kjeldahl procedure.¹¹

8. Plasma volume was ascertained by the technic of Gregersen and Stewart.¹²

CLINICAL MATERIAL

The occurrence and type of anemia were ascertained in 122 consecutively admitted patients with gastric cancer. Blood studies were made only after each

TABLE 1.—Relationship of Existence of Anemia to Site of Tumor

No. of Patients	Site of Tumor	Per Cent with Anemia
59	Lower third of stomach.....	64.5
15	Middle third of stomach.....	62.5

10	All of stomach.....	62.0

patient had been in the hospital for several days and was considered to be well hydrated. Of this group (a) marrow counts were made in 10 patients with macrocytic anemia, (b) daily total urobilinogen excretions were measured in 10 instances, (c) blood loss at operation was determined in 20 instances, (d) an attempt to induce reticulocytosis by the administration of liver extract was made in 4 and (e) the effect of considerable nitrogen retention on hemoglobin synthesis was studied in 4 patients.

RESULTS

Of 122 patients with gastric cancer, 64 per cent had abnormally low red cell counts and concentrations of hemoglobin. This incidence agrees well with that (59 per cent) found in a previous study of 100 patients

with the same neoplastic disorder.¹³ It is of interest to note that the site of the gastric tumor did not significantly affect the incidence of anemia in these individuals (table 1). Likewise, no definite correlation could be made between the existence of achlorhydria and the incidence or severity of the anemic state (table

TABLE 2.—The Existence of Gastric Achlorhydria in Patients with Gastric Cancer and Anemia

45	+	2.97	59.5

2). No attempt was made to correlate the occurrence and degree of the blood disorder with the probable duration of the neoplastic disease, for the latter factor could be estimated only very roughly by the onset of symptoms.

Of the 78 patients with anemia, the mean erythrocyte volume was macrocytic in 25, normocytic in 35 and microcytic in 18 (table 3). Of those with macrocytosis, hyperchromia, normochromia and hypochromia were found in 1, 24 and 0 respectively; of those with normocytosis all were normochromic, and of the cases of microcytic anemia 14 were normochromic and 4 hypochromic. Hence it would appear that, although the anemia of patients with gastric cancer varies widely with respect to the size of the red cells, the anemia in most instances is normochromic.

Microcytic anemia frequently may be the result of chronic blood loss or iron deficiency. Certainly there is reason to expect a gastric neoplasm to be the source of a continual and significant blood loss, and of the 18 patients with this type of hematologic disorder 10 either gave histories of or were found in the hospital to have a significant degree of gastrointestinal bleeding. This incidence of bleeding is considerably greater than that found for the patients with either normocytic or macrocytic anemia (table 4), but whether the total amount of blood lost by those with microcytosis was greater than that which occurred in the patients of the other groups cannot be estimated.

The anemia of these patients with microcytosis probably is not alone due either to a dietary deficiency

of iron or to an exceptionally great loss of it. This is suggested by the fact that the daily oral administration of 3 Gm. of ferrous sulfate for from thirty-eight to forty days to 3 of the patients with this type of hemogram increased the red cell counts only from 0.1 to 0.25 million and the concentrations of hemoglobin by from 6 to 13 per cent. At the end of this time all 3 still

had anemia, but this was then normocytic. It would appear reasonable to believe that had the anemia in these instances merely been on a basis of gastrointestinal bleeding the administration of iron should have been more effective.

Macrocytic anemia existed in 25 of the patients studied. The macrocytic anemia of patients with gastric cancer, like pernicious anemia, often has been attributed to an inadequate production of intrinsic factor. These two hematologic disorders differ, however, in many respects:

(a) In pernicious anemia the macrocytosis almost uniformly is associated with hyperchromia. This was not the case in patients with gastric cancer and macrocytic anemia included in the present study.

(b) Only 1 of the 25 patients with gastric cancer and macrocytic anemia had leukopenia or lymphocytosis; these leukocyte changes, on the other hand, are a frequent finding in cases of pernicious anemia in relapse.

(c) Of 10 patients with gastric carcinoma and macrocytic anemia, the marrow count failed to suggest in any instance the impaired maturation of erythroblasts characteristic of pernicious anemia in relapse (table 5).

(d) Finally, the intramuscular injection of adequate amounts of liver extract uniformly elicits a reticulocyte response in patients with pernicious anemia; in contrast, the daily parenteral administration of from 30 to 45 units of antianemic principle¹⁴ for from fifteen to eighteen days to each of 4 patients with gastric cancer and macrocytic anemia failed to induce any significant reticulocytosis (table 6). Since patients with gastric carcinoma are known to have considerable hepatic disorder, it is possible that their livers no longer may be able to synthesize, utilize or store the anti-anemic principle.¹⁵ When the livers of patients with various forms of hepatic disease are used as a source of antianemic principle in the treatment of pernicious

anemia in relapse, no significant reticulocyte rise is induced. Studies now are under way to ascertain the effects of hog gastric mucosal preparations on this blood dyscrasia.

Although both blood disorders are associated with a high incidence of gastric mucosal atrophy, gastroscopy

reveals that this abnormality also occurs as frequently in patients with gastric cancer who have either normocytic or microcytic anemia. Likewise achlorhydria (an almost constant feature of pernicious anemia) occurred even less frequently in the patients with gastric cancer and macrocytosis studied than it did in those with either normocytosis or microcytosis (table 7).

There is no reason to believe that the normocytic or macrocytic anemia of patients with carcinoma of the stomach is due to an increased rate of intravascular hemolysis. The total daily excretion of urobilinogen by 10 patients with gastric malignant tumors and anemia of these types was in no instance above 166.4 mg., and the average output only 79.5 mg. per day (table 8).

It has been demonstrated that macrocytic and normocytic anemias of the normochromic type frequently occur in patients with hepatic dysfunction.¹⁶ This observation has been confirmed here too in a group of 15 patients with cirrhosis of the liver and chronic alcoholism and in another of 4 persons with acute toxic hepatitis. A previous investigation of this series found considerable evidence of hepatic insufficiency also in patients with gastric carcinoma,¹⁷ and among the functions particularly depressed were those of albumin and prothrombin fabrication. Whether or not these patients, because of hepatic dysfunction, likewise have an

forced protein feedings produced a considerable nitrogen retention, and although plasma protein fabrication did take place the simultaneous production of hemoglobin probably was not in normal proportion. It has been shown by others² that protein administered to animals experimentally rendered hypoproteinemic and anemic

is preferentially diverted for hemoglobin manufacture, and synthesis of hemoglobin and plasma proteins takes place in a ratio of about 3:1. In 3 of the 4 patients with gastric cancer, however, for every gram of plasma protein synthesized during this period an increase only of from 0.2 to 2.0 Gm. of hemoglobin occurred, and in the fourth instance the hemoglobin concentration actually fell during the period of plasma protein fabrication (table 9). This experiment lacks, of course, adequate human control data and is only of a preliminary nature, but at the moment it does suggest a disturbance of hemoglobin synthesis in patients with gastric cancer. If the anemia in most patients with gastric cancer (those not due to considerable, continual blood loss) is on this basis, then its treatment probably should be that of general hepatic insufficiency. A uniform therapeutic regimen thus far has not been generally accepted, but most investigators of hepatic disease¹⁰ apparently believe that a diet high in protein and carbohydrate, plus supplements of a lipotropic nature and vitamin B complex, at least are necessary. The experience of this service has been that this dietary regimen often does increase the hepatic functional capacity of the patients with gastric cancer or hepatic

cirrhosis. It is too soon to state what the effect of these measures are on the associated anemia.

Blood loss at operation probably does not add significantly to the extent of the anemic state. In most instances this is quickly compensated for, if only temporarily, by an adjustment of plasma volume, so that

the concentration of red cells or hemoglobin is only slightly altered.

Of 20 patients submitted to surgery, gastrectomy and gastroenterostomies each were performed in instances; the average amounts of blood lost in their course were 140 and 130 cc. During the more extensive operative procedures of transthoracic resection of cardia tumors, subtotal and total gastrectomies, 2, 1 and 4 patients subjected to these respectively lost an average of 462.5, 232 and 194 cc. (table 10). In most instances the concentrations of hemoglobin on the day after operation were not seriously decreased from those in the preoperative periods. Nevertheless it is entirely worth while to estimate correctly the amounts of bleeding which occur during surgical manipulation. This is particularly true in elderly patients, who, because of cardiovascular insufficiency, cannot always tolerate the administration of large whole blood transfusions given to replace an overestimated amount of blood shed.

CONCLUSIONS

1. The anemia of patients with gastric cancer varies widely with respect to the size of the red cells, but in most instances it is normochromic.

2. There is reason to believe that the macrocytic and normocytic anemia of these patients is not on the same basis as that of Addisonian pernicious anemia but probably is related to the associated hepatic insufficiency.

York Avenue at Sixty-Eighth Street.

Health Problems on Tonga or Friendly Islands.—Very little milk is produced on the islands. There are no facilities for pasteurization. Facilities for cold storage are found only in Nukualofa, but even at that place the facilities are not nearly enough to insure adequate storage of perishable foods. Meats are inspected in some instances, but inspection is not universal and is not thorough enough to be relied on. Some fish which are normally edible are reported to become poisonous during the spawning season. In the Tonga Islands, as well as elsewhere in the Pacific, poisoning by the eating of fish in most cases is caused by fish which belong to the Tetraodontidae and which commonly are known as "puffer fish" or "balloon fish." The eggs of several species of Tetraodon are always poisonous, even when immature. The common belief that the bile and liver of this fish are poisonous is usually, but not always, true. The symptoms of Tetraodon poisoning are vertigo, headache, vomiting, diarrhea, paralysis and sudden death. Tongans suffer from a deficiency of vitamins A and D, calcium, iron and iodine. They do not like milk, eggs, fruit and green vegetables. Some fish is eaten but not a quantity large enough to supply the requirements of iodine. Foods necessary for an adequate diet could be produced in quantities sufficient to meet local needs, but habits of long standing in respect to choice of foods on the part of the natives make changes very difficult.—Simmons, James S.: *Global Epidemiology*, Philadelphia, J. P. Lippincott Company, 1944.

Clinical Notes, Suggestions and New Instruments

TREATMENT OF VINCENT'S ANGINA WITH SULFATHIAZOLE

LIEUTENANT COMMANDER WILLIAM W. MANSON (MC), U.S.N.R.
AND

LIEUTENANT COMMANDER IRWIN T. CRAIG (MC), U.S.N.R.

That Vincent's organisms are frequently found in smears taken from a normal mouth is now common knowledge. They have been found in about 75 per cent of adult mouths examined, in spite of the absence of symptoms of Vincent's angina or Vincent's gingivitis, by Stafne. Their presence in smears taken for microscopic study should not be a basis for a diagnosis of Vincent's angina in the absence of clinical symptoms and signs, but when a patient is seen who has a sore throat, elevated temperature, a membrane on the throat or tonsil with a necrotic tonsillar ulcer and a smear showing numerous fusiform bacilli, and *Borrelia*, it can definitely be stated that the Vincent's organisms are the cause of the condition.

Arsenicals, as well as bismuth, have been shown by Ludwick,¹ Farrell and McNichols,² Jewesbury,³ Farley⁴ and others to be far from the specifics that they were once considered in the treatment of infections of this type. There have been a great number of cases reported of syphilitic patients who have developed Vincent's angina while on their antisyphilitic treatment. This would indicate that arsenic and bismuth are not even inhibitory where Vincent's organisms are concerned when they are employed by the intravenous and intramuscular route.

Fellows⁵ employed sulfathiazole orally in conjunction with a topical application of saturated solution of neoarsphenamine in glycerin to the lesions and got good results in a series of 36 cases. Linton⁶ reported 4 cases treated with sulfathiazole dissolved on the tongue, and his results were so satisfactory and the time required for establishing a clinical cure so short that it was decided to adopt his recommended treatment at this activity, where man-hours are so important. By doing so, the treatment time on the average case of Vincent's angina has been cut from ten days to seventy-two hours.

This treatment consists of a 0.5 Gm. sulfathiazole tablet dissolved on the tongue every two hours during the day and two such tablets dissolved in the same manner every four hours at night. The temperature usually returned to normal in twenty-four hours and the symptoms had almost completely disappeared by that time. In spite of the clinical improvement, the treatment was continued for a total of seventy-two hours, except in very mild cases, when it was terminated at the end of forty-eight hours. A smear taken at this time either reported no Vincent's organisms or a pronounced reduction of the *Borrelia* forms. Treatment, however, was discontinued at seventy-two hours regardless of the findings on throat smear because the patient was clinically if not microscopically well. Lesions were invariably cleared up in ninety-six hours after beginning treatment.

There are many cases which could be included in this report if we reported all the cases in which the laboratory found Vincent's organisms on throat smear. However, only those cases which demonstrated a tonsillar ulceration with a grayish membrane which, on smear, showed great numbers of fusiform bacilli and spiral forms are included in this report. It is felt that only these cases represent true Vincent's angina of

the tonsil. Usually these lesions are unilateral. One case in our series showed bilateral ulceration of the tonsils. There was also 1 case which we listed as a recurrence though the possibility of a reinfection must be kept in mind in this case, since there was a period of two months' time without symptoms.

This series comprises 36 cases treated by the method described. No case was treated with sulfathiazole over seventy-two hours, the total dosage in these cases being 18 Gm. The milder cases received forty-eight hours of treatment for a total of 12 Gm. of sulfathiazole. Results were uniformly good in the two groups. Average sick days were 3.75 for this group, which is much shorter than that obtained with the older methods employed at this activity. These older methods included the use of neoarsphenamine locally as well as intravenously.

There were no cases of sulfonamide sensitivity in this series. Pilots and air crewmen were grounded for forty-eight hours following the discontinuance of the drug, since this measure is employed for all patients receiving any of the sulfonamide drugs.

The results have been so satisfactory in these cases that we have adopted this method as the routine treatment of all cases which demonstrated clinical Vincent's angina. The laboratory smear is employed only to confirm the diagnosis, since the finding of the Vincent's organisms alone does not constitute a diagnosis of Vincent's angina unless the clinical signs are present.

NOTE.—Since these cases were reported, 12 additional cases have been treated by the same method as described, without recurrences, for a total of 48 cases. These cases also showed extensive ulceration of the tonsil, and though the ulcer was not completely healed at the end of the seventy-two hours treatment, the patient was asymptomatic and the ulcer was seen to be cured on follow-up examination without further therapy.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., Secretary.

NIKETHAMIDE (See New and Nonofficial Remedies, 1944, p. 330).

The following dosage form has been accepted:
WILLIAM R. WARNER & Co., INC., NEW YORK
Ampul Solution Nikethamide 25% W/V: 2 cc. and 5 cc.

SULFADIAZINE (See New and Nonofficial Remedies, 1944, p. 178).

The following dosage form has been accepted:
WILLIAM R. WARNER & Co., INC., NEW YORK
Tablets Sulfadiazine: 0.5 Gm.

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1944, p. 608).

The following dosage form has been accepted:
AMERICAN PHARMACEUTICAL Co., INC., NEW YORK
Tablets Thiamine Hydrochloride: 5 mg. and 10 mg.

ASCORBIC ACID (See New and Nonofficial Remedies, 1944, p. 620).

The following additional dosage form has been accepted:
GEORGE A. BREON & Co., INC., KANSAS CITY, MO.
Tablets Ascorbic Acid: 50 mg.

PREMARIN (See THE JOURNAL, Aug. 19, 1944, p. 1098).
The following additional dosage form has been accepted:
AYERST, MCKENNA & HARRISON, NEW YORK
Tablets Premarin: 0.63 mg.

SURVIVAL ON A RAFT AT SEA

Water is the primary need for survival on a raft at sea. A man who ingests ample water but not food can, as pointed out by Ivy and his associates,¹ survive twenty to thirty days, provided he is not subjected to physical strain, to which fasting renders him unduly susceptible. An adult may survive lack of food for forty or more days under favorable conditions. The longest recorded period of survival at sea without water is eleven days. Ivy² points out that the space and weight which can be allowed to life saving gear aboard military aircraft is naturally limited. The parachute and rubber raft are most important, and next water. This lack of space has made water packed in cans inadequate.

With the opening of the Naval Medical Research Institute in October 1942, further investigations were undertaken. The suggestion that sea water could be ingested at a rate that did not cause emesis and diarrhea—an average of 800 cc. per day—or that it could be taken as a retention enema was physiologically unsound. In practice this method was found to increase the rate of dehydration of the body and disturb the electrolyte balance. The dechlorination method devised by Goetz converted the sea water to a 3.9 per cent solution of sodium citrate. The sodium citrate is converted in the body into sodium bicarbonate. The Goetz method maintained the body water better than is possible without ingestion of water, but the alkali reserve of the blood was raised to 71 to 77 volumes per cent and the urine became too alkaline. The continued ingestion of this water would prove to be injurious. Next an attempt was made to determine whether fresh water could be extended by the addition to it of some sea water. Ivy and his associates found that not more than 1 volume of sea water should be added to 4 or 5 parts of fresh water, the maximum limit being set at 200 cc. of sea

water or 6 Gm. of salt daily. Ivy showed that minimal daily water requirements under ordinary working conditions in a laboratory with enough carbohydrates to prevent ketosis (50 to 75 Gm.) ranged from 825 to 1,000 cc. in adults weighing from 55 to 75 Kg. Desalination of sea water next occupied the attention of the staff of the Navy Institute. The "Permutit" method, which was developed, involved the use of a single precipitation and the use of only one bag, into one end of which a filter was placed. This method yielded 4.5 volumes of potable water to 1 volume of chemical and equipment. A can of chemical and equipment having a volume of 700 cc. will yield 3,000 cc. of potable water. This amount of water will extend survival at least six times longer than the fresh water which is supplied in a can occupying approximately the same space. In an actual trial in which 21 men spent four days on rubber rafts at sea, this method met the requirements better than any other. The method was adopted by the various military and civilian aviation services.

In a previous communication Ivy pointed out that, although water was more important for survival than food, even a limited supply of food,¹ if properly selected, raises morale, provides appreciable energy and contributes to the conservation of the water supply. Ivy and his associates have developed a "tablet emergency ration" the three food components of which are sucrose-citric acid, sucrose-lipid-citric acid and sucrose malted milk tablets.³

THIOUREA AND EXPERIMENTAL CARCINOGENESIS IN THE THYROID

The production of carcinoma of the thyroid in rats¹ is of extraordinary interest to all students of carcinogenesis and of thyroid disease. Wilson, De Eds and Cox² at Stanford University discovered that 2-acetaminofluorene fed to rats produced neoplasm of many organs and tissues. Bielschowsky,³ working in Great Britain, confirmed their observations that the implanted substance did not cause local inflammation or new growths, while feeding caused cancers of the external auditory canal, the lungs, salivary glands, liver, pancreas, bladder and breast as well as leukemias and sarcomas. All this occurred in a species with a low spontaneous occurrence of tumors and from an agent that does not cause cirrhosis or other degenerative changes. Obviously a carcinogen of extraordinary potency has been discovered by the American pathologists.

3. Bielschowsky, F.: Distant Tumors Produced by 2-Aminofluorene and 2-Acetylaminofluorene, British J. Exper. Path. 25: 1 (Feb.) 1944.

1. Ivy, A. C.; Fitcher, Palmer H.; Consolazio, W. V.; Pace, Nello, and Gerrard, Elizabeth J.: A Tablet Emergency Ration for Lifeboats and Rafts, U. S. Nav. M. Bull. 42: 841 (April) 1944.

2. Ivy, A. C.: Contributions to Survival on a Raft at Sea, Proc. Inst. Med. Chicago 15: 173 (Dec. 15) 1944.

None of the cancerous animals in either series had tumors of the thyroid gland. Nor did cancers occur in rats fed thiourea by Bielschowsky.¹ Rats fed both thiourea and 2-acetaminofluorene did show adenomatous or anaplastic invasive epithelial tumors. Thiourea alone produced, as it does in man and other animals, an intensely hyperplastic thyroid gland. Thus a chemical that causes hyperplasia limited to a single organ prepared that organ for carcinogenesis by a chemical which normally is effective only on other tissues. As thiouracil is being given to men, and as acetaminofluorene was under consideration as an insecticide, these results have not only theoretical but practical significance.

Occupational cancers of man led the Japanese to the discovery of experimental chemical carcinogenesis. The frequency of histologic neoplasms in hyperplastic cirrhotic livers, in hyperplastic prostates and in nodular goiters is recognized by most pathologists. The importance of hormonal chemical agents in carcinogenesis, stressed first by Leo Loeb, has been widely confirmed in human experience and animal experiment. Human cancers, and those of most mammals, have not been found to be transmitted by infection or by filtrable agents. The truly startling effects of acetaminofluorene on various tissues of the rat, and the necessity for hyperplasia as a concurrent factor in thyroid carcinogenesis, reemphasize the importance of chemical carcinogens and of hyperplasia in predisposition to cancer in man.

If viruses assume any role in the thyroid cancers evoked by these two chemicals, it must be a role different from that of the filtrable agents from leukemic or tumor cells of birds or rabbits, since these regularly reproduce specific cellular reactions if injected into other members of the same species. It is just as improbable that chemical carcinogens act by the activation of local latent viruses as that chloroform or phosphorus damages the liver, or mercury the renal tubules, by the activation of latent viruses in these tissues. Herpes virus is apparently latent in nearly all human beings and is activated by many factors, some of them trivial disturbances of bodily functions. In toxoplasma encephalitis of the newborn and in congenital syphilis, latent infectious agents manifest themselves in the rapidly growing fetal tissues. The possibility cannot be excluded that some types of hepatitis, encephalitis, nephritis and even of cancer may be due to activation of latent viruses. But when a carcinogen evokes cancers in nearly all the tissues of nearly all the members of a species in which spontaneous tumors of most tissues are extremely rare, it must be conceded that viruses do not assume a role in the phenomena or that the latent cancer viruses are as all pervasive and therefore of as little specific significance as salt and water.

The thyroid carcinogenesis reported by Bielschowsky raises a practical question as to the possible hazard of using thiouracil in toxic diffuse goiter except as prelimi-

nary to resection of the gland. In old and even in middle aged patients some adenomas are usually found. Microscopic studies are said to reveal carcinomas in 3 to 8 per cent of grossly adenomatous goiters, and even in hyperplastic thyroids removed for toxic diffuse goiter occasional cancers have been found arising in minute adenomas.⁴ Since thiourea and acetaminofluorene together evoke rapidly growing tumors, which neither alone produces, may not thiouracil, together with the dyscrasia which causes adenomas and "carcinoma in situ" in so many thyroids, lead to clinical cancer when prolonged action is maintained in older patients? This is a problem which all thyroid clinics using thiouracil will undoubtedly keep under the closest surveillance.

BIOLOGIC VALUE OF SOY PROTEIN

This country, with its vast food producing capacity and food stores, has developed average food habits at a level not even approached elsewhere. In the United States the soybean has not been the staple, main source of nutriment that it is to large portions of the world's inhabitants. Soybean flour has been increasingly included in breads and pastries; the small increase in protein, the "richer" color and the nutty flavor imparted by modest admixture of this material are some of the reasons for the growing diversion of soybeans to the production of low fat soyflour. The possibility, emphasized by the war, that the large quantities of soybeans raised in the United States might provide human food which could be substituted for more expensive or less readily available nutrients ordinarily consumed has received attention in the present national emergency.

Of particular interest in this connection is the suitability of the protein of soybeans for human consumption. The dry seeds contain about 34 per cent of protein; as some 216,000,000 bushels was produced in 1944, this legume represents a tremendous reserve of food protein, provided it is physiologically available in the body. Although the long history of the use of soybeans as human food would seem to argue a priori against any considerable detrimental effect, convincing evidence of its value in this respect has been lacking. In a recent experimental study¹ comparison of the net retention of nitrogen by adult human subjects when soybeans provided the protein with the same values when whole egg was the main protein of the experimental diet was measured. The assumption was made that the protein of the whole egg is completely digested, absorbed and utilized, in which case the fecal and urinary nitrogen when egg was consumed would represent the evidence of irreducible protein metabolism.

4. Goetsch, Emil: A New Concept Regarding the Origin of So-Called Primary Carcinoma of the Hyperplastic Thyroid, *Ann. Surg.* **118**: 843 (Nov.) 1943.

1. Cahill, W. M.; Schroeder, L. J., and Smith, A. H.: *J. Nutrition* **28**: 209 (Sept.) 1944.

Soybean protein in three forms was studied: as whole cooked, field grown beans, as commercial low fat soy-flour and as a prepared soybean milk. The true digestibility of the protein in the three products was 90.5, 94.0 and 89.6 per cent respectively when compared to whole egg protein. These values are somewhat lower than those for food proteins of animal origin but superior to those usually observed with other legume protein. With respect to the biologic value of soybean protein, the values were 94.5, 91.7 and 95.3 per cent respectively, indicating that, tested under the conditions cited, soybeans in the forms employed can be considered an excellent source of protein in adult human nutrition.

In view of the current enormous production of soybeans, our national nutrition, as far as protein is concerned, is amply safeguarded against an extensive emergency. Likewise, in the occasional instances in which usual food protein is not well tolerated, the soybean offers additional possibility of dietotherapeutic adjustment with respect to protein nutrition.

Current Comment

GRAMICIDIN S

The latest result of the search for antibacterial substances in fungi and other microbes appears to be the isolation by Russian investigators¹ of a crystalline bactericidal polypeptide from the liquid culture of an aerobic sporulating soil bacillus of the *Bacillus brevis* type described by Stokes and Woodward.² This strain was one of several hundred strains of sporulating bacilli from Russian soil studied with respect to antibacterial action but with otherwise negative results. The alcoholic extract of the acid precipitate of liquid cultures of the bacillus yields the active principle in easily obtained thin, colorless crystalline needles, alcoholic solution of which diluted with water has bacteriostatic and bactericidal effects on staphylococci, streptococci, pneumococci and some other gram positive bacteria as well as on a number of gram negative bacteria, including *Proteus vulgaris* and *Escherichia coli*. This antibacterial substance has been named Soviet gramicidin or gramicidin S. Chemically it differs from the gramicidin of Dubos and from tyrocidine hydrochloride;³ it is a stable substance; its activity is not destroyed by autoclaving. Experimentally it was found to protect guinea pigs and rats against infection with the gas bacillus. Sergiev⁴ reports on its clinical use by local application in 1,500 cases in ten Soviet hospitals. Solutions in water or in 70 per cent alcohol, containing in each cubic centimeter 400 mg. of gramicidin, were used; also ointment of a

4 per cent alcoholic solution of the dry substance diluted fifty times with castor oil. Favorable results were obtained in suppurations of soft tissues and in skin grafting, osteomyelitis, empyema, peritonitis and skin infections. In the latter the best results followed the application of dilute alcoholic solutions. Conclusions are not drawn with regard to the prophylactic value of gramicidin S, but all wounds treated prophylactically with it "healed by first intention." Toxic effects did not result from the external use or the introduction into the pleural or peritoneal cavities of the watery solution of gramicidin S. Alleviation of pain is mentioned as a characteristic feature of its use. The outcome of further observations on the value of gramicidin S will be of great interest.

EPILEPSY—ACCURATE INFORMATION FOR THE PUBLIC

The Public Affairs Committee, with the aid of a number of leaders in the field of epilepsy, has made available a useful, realistic consideration of the disease for the lay reader.¹ After description of a typical case the report discusses what epilepsy is and how it got its bad name. The pamphlet suggests consideration to changing the name of the disease because of its bad connotation but rejects the suggestion. Causes and diagnostic methods are next discussed, including a simple, clear explanation of the electroencephalograph. Modern methods of treatment are outlined. The expensiveness of quackery is emphasized. Useful books for epileptic patients are listed. Sensible advice about sending children with seizures to school and about marriage and parenthood are given. An encouraging survey of industrial opportunities for the epileptic is outlined. All in all, this is a fine, brief and inexpensive pamphlet which should be of great use to patients. Physicians dealing with the epileptic and their families might find it decidedly advantageous to give a copy of this pamphlet as a planned part of the therapeutic regimen.

TARTARIC ACID

A recent note¹ on foreign trade lists the items of largest importation from Italy since the present war began. Among such items as essential oils, red squill, onion seeds and wine is 112 tons of argol. This substance is crude potassium acid tartrate; it crystallizes as a thick crust on the walls of wine vats and to date has been the main source of tartaric acid. In view of the wide use of this organic acid in the food industry and in medicine, it is of more than passing interest that such an important substance should depend on a source which is so readily curtailed by war in restricted localities. As happened in connection with citric acid after the last war, efforts are now being made to adapt new biochemical principles to the synthesis of organic acids which will be satisfactory substitutes for tartaric acid in the various ways in which it has entered into the technology of food and pharmaceuticals.

MEDICINE AND THE WAR

ARMY

SKIN DIPHTHERIA IN SOLDIERS

Major Gen. Norman T. Kirk, Surgeon General of the Army, recently reported that minor epidemics of skin diphtheria which have broken out among American soldiers in the Pacific areas have been brought under early control. While these epidemics have not been of serious consequence, the problem of skin diphtheria is one of serious potential significance.

Lieut. Col. F. R. Dieuaide, chief of the tropical disease treatment branch of the Surgeon General's Office, who recently returned from a three months visit in three Pacific theaters, described a small epidemic of skin diphtheria in the New Hebrides. It is thought that the epidemic arose from carriers. From this source in the skin of 1 person organisms are readily transferred to skin lesions in other persons or to the throats of susceptible soldiers. Colonel Dieuaide said that this disease has been found in this war in North Africa, in India and in the Pacific. In general it is so rare that it is unknown to the public at large, including many doctors. Inability to take proper hygienic care of the skin and superficial wounds and living in close quarters give rise to its spread. The great importance of skin diphtheria, Colonel Dieuaide said, lies in the danger that it may cause epidemics of ordinary diphtheria in susceptible soldiers who would suffer the usual severe illness. A small number of such cases and a few deaths have occurred.

MILITARY TRAINING FOR WACS

The War Department announced recently that all military training for the Women's Army Corps will be consolidated at the First WAC Training Center, at Fort Des Moines, Iowa, by April 1. The Third WAC Training Center, at Fort Oglethorpe, Georgia, will be discontinued by that date. Only WAC training activities at Fort Oglethorpe are affected by this consolidation.

Consolidation of military training facilities is in line with the Army's WAC recruiting program for 1945, which will stress the enlistment of women possessing specialized skills rather than large numbers, together with those qualified for training and service as medical and surgical technicians in army hospitals. The efficient and economical utilization of training personnel and facilities will require only the one WAC training center at Fort Des Moines for basic and specialized military training in light of reduced enlistment quotas in 1945. Medical and surgical technicians will receive specialized training in army medical department schools and hospitals after completion of basic military training.

ARMY AWARDS AND COMMENDATIONS

Captain Alan R. Bleich

The Soldier's Medal was recently awarded to Capt. Alan R. Bleich, formerly of Brooklyn, for saving the life of a pilot caught beneath a burning plane. Disregarding his own safety and the imminent danger of the burning plane exploding, Captain Bleich crawled beneath the plane as it was hoisted to cut loose Capt. Jake L. Wilk, Houston, Texas, pilot. Captain Bleich was medical officer of the day (September 28) and was seated in his jeep while the P-38s were taking off on a bombing mission against targets in Germany. As Captain Wilk took off, it was evident that he was experiencing engine trouble and was going to have to make a forced landing. Captain Bleich immediately started for the end of the runway and found that Captain Wilk's plane had overturned and he was pinned under the canopy. Grabbing a shovel, Captain Bleich dug the dirt away from the canopy so that the pilot could get some air. At the same time he directed the crash crew to pass a chain under the nose of the plane so that it could be lifted and the pilot

taken out. Another fire then broke out around the left engine. Without hesitation, Captain Bleich got under the plane and cut the pilot loose from his safety straps. While under the plane there was imminent danger of the chain slipping, crushing both of them. Dr. Bleich is a licentiate of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow, 1940. He entered the service Oct. 29, 1942.

Major Sidney Schnur

Major Sidney Schnur, formerly of Houston, Texas, has been awarded the Bronze Star Medal. According to the citation, "Major Schnur showed great initiative, ingenuity and ability in maintaining the health of the command. By successfully raising the sanitation level of the Air Force field installations to an unusual degree, by initiating and following through a malaria control program which has actually controlled the disease, by persistent efforts and novel procedures in the control of venereal diseases, by improving the quality of food served in field messes through introduction of new methods of procurement and distribution, by devising and supplying escape first aid kits to combat personnel and by his continuous research in various fields of aviation medicine Major Schnur lowered the noneffective rate from disease to a bare minimum. Major Schnur's devotion to duty and his successful and tireless efforts in the fields of health, hygiene and sanitation reflects great credit on the armed forces of the United States." Dr. Schnur graduated from New York University College of Medicine, New York, in 1935 and entered the service in October 1940.

Colonel Albert R. Dreisbach

The Legion of Merit was recently awarded to Col. Albert R. Dreisbach, formerly of Washington, D. C., for "services from February 1942 to October 1944 as assistant director and director of the division of health and sanitation in the Office of the Coordinator of Inter-American Affairs. He contributed greatly to the joint war effort of the American republics through his effective direction of the cooperative health and sanitary program, designed to support military operations, production of strategic materials and morale in the tropical areas of the American republics. His initiative, imagination and loyalty contributed to the application of health measures in eighteen of the Central and South American republics, safeguarding the interests of both the United States and these countries." Dr. Dreisbach graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1931 and entered the service June 17, 1931.

Colonel William H. Huntington

Commander, Order of the Crown of Italy, has been conferred on Col. William H. Huntington, formerly of Portland, Ore., and now commanding officer of a station hospital with the Peninsular Base Section, the first American supply base established on the European mainland. There was still fighting in Naples when the section arrived, and it was also confronted with a serious epidemic of typhus. Quantities of DDT powder were rushed in, delousing stations set up throughout the populated districts, and by virtue of fast and vigorous work, what might have been a disastrous epidemic was averted. Dr. Huntington graduated from George Washington University School of Medicine, Washington, D. C., in 1910 and entered the service Aug. 22, 1941.

Captain Henry Clay Robertson Jr.

Capt. Henry Clay Robertson Jr., formerly of Charleston, S. C., was recently awarded the Bronze Star Medal. The award was made for "meritorious achievements in connection with extensive military operations" against the enemy. Dr. Robertson graduated from the Medical College of the State of South Carolina, Charleston, in 1935 and entered the service July 23, 1942.

AMERICAN COLLEGE OF SURGEONS
DEFERS WAR SESSIONS

The American College of Surgeons has deferred for the time being its 1945 series of War Sessions, four of which were to have been held in February, according to an announcement by Dr. Irvin Abell, chairman of the Board of Regents. Dr. Abell states that plans had been completed for the February meetings because earlier indications were that sessions of a strictly educational nature, limited to relatively small local areas, would be sanctioned by the War Committee on Conventions, but it now develops that the transportation crisis is so acute that even this type of meeting should be omitted in order to help the war effort, and the College is glad to cooperate with the agencies responsible for the movement of military personnel and supplies.

The American College of Surgeons has voluntarily omitted its annual clinical congress ever since the United States entered the war, in order to aid the war effort by minimizing the demands on transportation facilities. The War Sessions were devised as a wartime expedient to preserve the educational values as far as possible, with greatly lessened demands on hotel and travel services.

The February meetings were to have been held in St. Louis on the 2d, in Louisville on the 5th, in Milwaukee on the 7th and in Cleveland on the 27th.

SURPLUS FIRST AID DRESSINGS

The Office of Surplus Property of the Treasury Procurement Division has announced that it is imposing no restrictions on the use of the 28 million Carlisle first aid dressings recently placed on sale by its medical and surgical division. This action is based on the following letter, which the Treasury received from the Food and Drug Administration:

We have reviewed the labeling and have observed the dressings of the "small first aid dressing U. S. Army Carlisle Model sterilized" and the labeling of the "large size first aid dressing U. S. Army Carlisle Model sterilized" which you submitted to us today.

So far as the requirements of the Federal Food, Drug and Cosmetic Act are concerned, assuming that the lot of merchandise involved does in fact consist of sterile first aid dressing, there is no objection to the sale of this material for use by the medical profession or by the lay public. We might add, however, that we doubt whether there will be any considerable demand for dressings of this size by the lay public.

While the Treasury Department cannot warrant that each of the dressings is sterile, the announcement by the Office of Surplus Property was promoted by the fact that advertisements of this merchandise had previously stated that the dressings were not to be used for medical purposes.

The Treasury Department has extended until 2 p. m. Central War Time, February 17, the time during which bids will be received on this merchandise at the Procurement Division Regional Office, Cincinnati, and persons who have already bid may, if they so desire, revise their bids in light of the new ruling.

AMERICAN COMMITTEE FOR MEDICAL
AID TO ITALY

In reference to the notice in THE JOURNAL of Dec. 23, 1944, page 1097, concerning the organization of Medical Aid for Italy, the president of the committee, Dr. Arturo Castiglioni, professor at Yale University, wishes to express his thanks to the many doctors who sent him instruments, medicine and other gifts. The need in Italy is extreme and the mortality of children has assumed the rate of 47 per cent. The rate of tuberculosis has tripled in recent months. There is also an urgent request from Italian doctors for American medical reviews and medical books, which have not been brought into the country since 1939. All gifts will be conveyed to Italy through the American Relief for Italy, Incorporated, or will be used for the purchase of medicine and instruments. All donations will be most gratefully accepted and should be addressed to the American Committee for Medical Aid to Italy, 225 Lafayette Street, New York 12, N. Y.

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

Gardiner General Hospital, Chicago: Diseases of the Intestinal Tract: Medical and Surgical Diagnosis and Care, Dr. Warren H. Cole and Walter L. Palmer, February 14; Pleural and Peripheral Nerve Injuries, Dr. Adrien H. Verbruggen, February 28.

Station Hospital, Fort Sheridan, Ill.: Dermatologic Diseases, Drs. James H. Mitchell and Francis E. Sencar, February 15; Burns and Plastic Surgery, Drs. Wayne B. Slaughter and Volney B. Hyslop, February 28.

Mayo General Hospital, Galesburg, Ill.: Malignancies in the Army Age Group: Medical X-Ray and Surgical Diagnosis and Treatment, Drs. Danely P. Slaughter and George J. Rukstuter, February 14; Endocrinology, Dr. Willard O. Thompson, February 28.

Station Hospital, Camp Ellis, Lewistown, Ill.: Wound Healing and Tendon Surgery, Drs. Hilger P. Jenkins and Alfred Rasmussen, February 14; Mental Hygiene and the Prevention of Neuroses in War, Capt. Charles O. Sturdevant, February 28.

Regional Hospital, Chanute Field, Rantoul, Ill.: Blood Dyscrasias; Malaria; Filariasis, Drs. Raphael Isaacs and Harry Jacobs, February 14; Diseases of the Kidneys: Urological Tract, Drs. Laurence E. Hines and Norris J. Heckel, February 28.

Station Hospital, Harding Field, Baton Rouge, La.: Psychosomatic Medicine, Dr. Theodore Watters, February 8; Vascular Diseases, Dr. Howard Mahorner, February 8; Fractures of the Ankle, Lieut. Col. Samuel Terhune, February 8; Amputations, Dr. Rawley Penick, February 8.

HOSPITALS NEEDING INTERNS
AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Administration Service:

(Continuation of list in THE JOURNAL, January 27, page 220)

GEORGIA

Grady Memorial Hospital, Atlanta. Capacity, 720; admissions, 141. Mr. Frank Wilson, Superintendent (residents—medicine, obstetrics, gynecology).

ILLINOIS

Holy Cross Hospital, Chicago. Capacity, 161; admissions, 4,199. Sister M. Dorothea, R.N., Superintendent (3 interns, July 1).
Illinois Masonic Hospital, Chicago. Capacity, 186; admissions, 1,172. Mr. William H. Tenney, Superintendent (2 interns, July 1).

MASSACHUSETTS

St. John's Hospital, Lowell. Capacity, 200; admissions, 4,407. Sister Angelica, R.N., Administrator (3 interns, July 1).
Belmont Hospital, Worcester. Capacity, 250; admissions, 1,061. Dr. Huston K. Spandler, Superintendent (resident—communicable diseases, July 1).

MICHIGAN

Grace Hospital, Detroit. Capacity, 549; admissions, 17,792. Dr. J. H. Law, Director (residents—surgery, urology).
St. Mary's Hospital, Grand Rapids. Capacity, 315; admissions, 7,570. Sister Mary Grace, Superintendent (2 interns).

MISSOURI

Menorah Hospital, Kansas City. Capacity, 145; admissions, 2,707. Dr. E. Kirsch, Administrator (interns).
Jewish Hospital, St. Louis. Capacity, 303; admissions, 6,704. Miss Florence King, Administrator (residents—surgery, obstetrics-gynecology).

NEW YORK

St. John's Hospital, Brooklyn. Capacity, 250; admissions, 3,699. Mr. E. Reid Caddy, Director (interns, July; April 1946).
St. John's Riverside Hospital, Yonkers. Capacity, 220; admissions, 4,429. Mr. S. Chester Fazio, Superintendent (2 interns).

PENNSYLVANIA

St. John's General Hospital, Pittsburgh. Capacity, 250; admissions, 5,125. Sister M. Baptista, Superintendent (3 interns, July 1).

WASHINGTON

St. Luke's Hospital, Spokane. Capacity, 335; admissions, 5,000. Mr. Gordon W. Gilbert, Administrator (2 interns, July 1).

ORGANIZATION SECTION

ANNUAL CONFERENCE OF SECRETARIES AND EDITORS OF CONSTITUENT STATE MEDICAL ASSO- CIATIONS

SATURDAY MORNING SESSION, NOVEMBER 18

DR. D. L. CANNON, Montgomery, Ala., Presiding

(Concluded from page 230)

Radio Broadcasting by the Medical Profession

DR. A. S. BRUNK, Detroit: When I speak of "radio advertising by the medical profession" I mean advertising in its commercial sense—by the purchase of time over the air to bring a message about medicine and a "plug" for the medical profession and its philosophy. The Michigan story begins with the levy of a special \$10 per capita assessment by the Michigan State Medical Society House of Delegates at its September 1943 session. The assessment was effective for the calendar year 1944. This assessment was earmarked for public education. The activity included a "School of Information" for county society officers and key men, the purchase of thousands of pamphlets, a contribution to the Michigan Health Council (which is an agency that informs the public through a general educational program what the medical society and the hospital association and the Michigan Hospital and Michigan Medical Service are doing to meet the health needs of all the people in our state). But the greatest activity from the assessment was the program of radio advertising sponsored by the state medical society at a cost of \$10,000.70. A special Committee on Radio, composed of three members, was appointed.

The chairman, who practices medicine in Detroit, had for years obtained gratifying results from the radio advertising of a flourishing commercial business which he had inherited. He had the experience and the practical touch. He recommended the placing of the program in the hands of an advertising agency equipped and interested in doing the job. Such an agency, which had served the dental profession of the state in its fight against advertisers, was enlisted. Soon twelve Michigan stations were lined up for two five minute broadcasts each per week for thirteen weeks. The radio stations were chosen geographically so that every section of the state was covered.

The twenty-six five minute presentations were dramatized sequences of an educational nature. The theme of the skits depicted the benefits to the public of the present and proposed medical availabilities as contrasted with the federal bureaucratic compulsory forms of medical practice. Subject matter of some of the skits included anesthetics, appendicitis, blood plasma, bubonic plague, cataracts, insulin, diphtheria, bone fracture, malaria, penicillin, rabies, rickets, spinal meningitis, plastic surgery, typhoid and subdural hematoma. The advertising agency developed, produced and transcribed the dramatized episodes under the supervision of the Michigan State Medical Society's Special Committee on Radio. Most of the ideas depicting medical incidents in the daily lives of the people originated in the minds of the members of the committee or of other medical men interested in the program. Professional radio actors of high histrionic ability were used. Each transcription had the following introduction: "Presenting a dramatized epic in the history of American Medicine and its application by American Physicians." The sequence was followed by the following plug: "American Medicine, the private practice of which represents the cumulative knowledge of decades, the heritage of centuries, the sacrifices and discoveries of countless individuals, has made the United States the healthiest country in the world. Spinal meningitis, diphtheria, smallpox, typhoid fever and other fatal diseases, scourges of yesteryear, are today either preventable or curable,

a credit to the tireless efforts of the American medical profession. Thirty-seven states now have voluntary prepayment medical or hospital plans developed by the medical profession and the hospitals. No theoretical plan, government controlled and operated, and paid for by you, should replace the tried and proved system of private practice now in use."

The program began over the twelve Michigan stations on August 1 and ended over Detroit's WXYZ on November 15. The results will be of interest to you. Toward the end of the series a spot or chain break (of about twenty-four words) was made after each presentation over all the twelve stations. This announcement offered something free to all listeners in order to ascertain listener interest. That which was offered was a copy of a recent booklet published by the Michigan Health Council containing the highlights of the Michigan Survey of Public Opinion concerning Medicine, which poll had been made by the Health Council at a cost of \$9,500. To date but a small number of requests have been received for these booklets, which is understandable, as there have been only two announcements over outstate stations and one from Detroit. However, our agency advises us that recent surveys of the various stations over which our program is broadcast show a combined potential listening audience of 1,250,000 people, or approximately 20 per cent of Michigan's population.

We feel that Michigan's experiment in radio advertising of the medical profession has been fruitful. Some of the people now know there are two sides to the question of distribution of medical care and, further, that the solution does not lie in the visionary panaceas offered by self seekers or dreamers who know little or nothing about medical practice and its intricate ramifications but in a thoughtful, painstaking evolution being worked out by the medical profession of the United States. Many now realize that private practice, aided by supplementary features (such as Michigan Medical Service with its 700,000 subscribers), are to be preferred—for their own good—than compulsion and further taxes out of Washington. I myself feel that the experiment has proved its worth and the Michigan State Medical Society will continue its radio advertising in the coming year.

Radio is a powerful vehicle, recognized by business, industry and even by politicians. Its value must not be overlooked or underestimated by the medical profession. Its use on a commercial basis—call it "propaganda" if you will—must be grasped by medical organizations now. The ear of the people must be reached today, not after the politicians have sold them a bill of cheap goods—via the radio!

If requested, assistance will be freely given to other state medical societies who may be interested in developing a similar program of radio advertising.

DISCUSSION

DR. OLIN WEST, Chicago: The American Medical Association itself has long maintained a nationwide broadcasting program and within the last several months has provided transcriptions for the use of medical societies and some for the use of some other groups. Those transcriptions are being rather freely used. Some of the medical societies seem to think that they have been extremely helpful. As far as I know, none of the other state programs have put on a paid broadcast. It is a question that seems to me to be of great interest, as to whether it is not a duty of the radio and the press to help in the dissemination of helpful, authoritative information about health matters. I do not know whether the time will ever come when the organized medical profession over the nation will wish to engage in a program similar to this, but I do agree with Dr. Brunk that the radio is a powerful instrument and that, properly used by the medical profession, it can have a tremendous effect in promoting the interest of medicine and thereby promoting the interest of the public.

DR. W. F. DONALDSON, Pittsburgh: I wish to express my personal gratitude to the Michigan Medical Association for its enterprise and enthusiasm and for the extent to which its

entire membership has contributed to this effort. Pennsylvania has for a number of years carried on as far as possible, not in the name of the state medical society but of many component medical societies, these instructional health programs. I appreciate just exactly how difficult it is to keep up the interest of state medical societies in providing the programs for the numerous broadcasting stations that are scattered throughout a state like Pennsylvania. Recently the American Medical Association has come to our rescue and we are using these transcriptions, or platters. It is astonishing the way these small broadcasting stations in towns of anywhere from 20,000 to 50,000 people like to receive these platters. We have a constant demand for them. I only hope that other state medical associations are using them as enthusiastically as we are in Pennsylvania. I want to express again my personal interest in this movement in Michigan. I do not know how soon I might be able to persuade Pennsylvania doctors to subscribe to the extent of \$10 apiece for such an experiment, but I am sure that it has great possibilities, and what we need above all things is persistence.

DR. W. T. BROCKMAN, Greenville, S. C.: I believe that, as somebody said, medicine is gradually being maneuvered into something that is entirely different from our tradition. I think that in South Carolina we are hungry for some kind of a change. We realize that we must make a change. Recently our live secretary has formulated and brought before our council a ten point program to acquaint the public better with what we are trying to do. In a modest way we started out with a few radio programs. I certainly am pleased to hear the Michigan doctor tell us about how well they have done this. It is going to stimulate me as president-elect of my society to push this movement. I think we have leaned backward in our modesty for a long time and that, regardless of how much we dislike to become bold and get out in front, we are going to have to do it in a dignified, modern way, as has been suggested here by our Michigan friends.

MR. T. A. HENDRICKS, Indianapolis: May I ask one question? What is the reaction to sponsored programs, that is, to programs sponsored by a commercial company? For a number of months we in Indiana have put on programs on a sustaining basis, that is, we do not get a good hour on the radio. We do not pay anything for our time. We have a company that sponsors our program. We produce it, we write the script. It is merely sponsored by a commercial company. We can get a good hour on the radio. What is the reaction to such an arrangement?

DR. STANLEY B. WELD, Hartford, Conn.: You have heard Dr. West and Dr. Donaldson refer to radio programs not paid for, and I am sure that is the universal or pretty nearly the universal custom throughout the state. I wanted to ask Dr. Brunk just why the Michigan State Society felt it necessary to have a paid program.

DR. A. S. BRUNK, Detroit: First, I want to thank those who have discussed the paper and shown an interest. I like the expression that the doctor from South Carolina used when he said that medicine is being maneuvered into a change. That is true and, as I see it, it is time that the medical profession gets immediately on the job and does something to try to guide that change. I am afraid that if it is not done promptly it may be too late. Concerning the question asked by Mr. Hendricks of Indiana as to what the difference is between a paid radio program and one sponsored by some commercial organization, I do not think there is any difference. Your commercial organization pays for the time as I understand it and it just saves the medical profession that much expense. They do get better hours because they are being paid for. We, of course, have the scientific programs which are donated by the radio station in Michigan and we don't get good times. The other question that was asked was why we thought it necessary to pay for radio broadcasting. Well, it is for the same reason that I have just stated, that is, you get better time and you can control the entire program. You can put on what you will. You cannot put on a commercial program over the radio without paying for it. This is a commercial program and not a scientific program. The radio stations will not donate time for commercial programs.

Washington Letter

(From a Special Correspondent)

Jan. 29, 1945.

General Hawley Appeals for Nurse Enlistments

A personal appeal to every nurse in the United States who is not in uniform was made by Major Gen. Paul R. Hawley, chief surgeon, European theater of operations, in a broadcast from Washington, to encourage enlistment in the Army Nurse Corps. Nurses in the European theater, he said, are "getting tired. . . . They are working rarely less than twelve hours a day and frequently as long as sixteen. They are making a record that is the most glorious page in the history of nursing. They are not complaining, but they cannot stand this strain indefinitely." General Hawley said that his appeal was "in behalf of thousands of wounded American boys—and, I am afraid, thousands more who will be wounded after this war is ended. These are the ones who suffer from the critical shortage of nurses. And this shortage is getting greater each day."

Improvement of Child Adoption Laws Urged

Review and improvement of laws relating to child adoption is urged by Katharine F. Lenroot, chief of the Children's Bureau, United States Department of Labor, in regard to the bureau's recommendations as to essentials of adoption laws and procedures. Not more than a fourth of the states have adoption laws that approximate the standards believed necessary by the bureau for adequate protection, she said. The following principles were recommended in adoptions to safeguard interests of all three parties concerned, the child, the natural parents and the adopting parents: 1. Adoption proceedings should be before a court dealing in children's cases. 2. The court should have the benefit of state welfare department study and recommendations in every proposed adoption. 3. Consent should be obtained from the natural parent. 4. Court hearings should be closed to the public. 5. A period of residence in the adoption home should be required before issuance of the final adoption decree. 6. Provision should be made for removal of children from homes found to be unsuitable. 7. Safeguards should be provided in related laws, such as relinquishment of parental rights, regulation of child placing services, determination of guardianship and custody of child.

Women Needed for Special Hospital Duties, Says Mrs. Roosevelt

Women are needed for other duties in military hospitals besides nursing, Mrs. Roosevelt said in her column *My Day*, which is released from Washington. They are required to become laboratory technicians, nurse's aides and in other ways to supplement the work of the registered nurses. "If a girl feels that she wants to work in hospitals but still does not want to take a nurse's training," Mrs. Roosevelt said, "there are many possibilities open in the armed services."

Public Health Nurses Paid High Tribute

High tribute to the work of public health nurses was paid by Dr. J. W. Bird, president of the Medical and Chirurgical Faculty of Maryland and secretary of the Montgomery County Medical Society. "They are of the greatest assistance to us these busy days, and long before the present emergency they were doing the same magnificent job, modestly and without acclaim," he said, in the course of an interview over the Blue Network.

Wallace Includes Medical Care in "Bill of Rights"

Before the Senate Commerce Committee, which voted 14 to 5 against President Roosevelt's nomination of Henry Wallace as secretary of commerce, Mr. Wallace expounded his economic bill of rights, sixth item of which was "the right to adequate medical care and the opportunity to achieve and enjoy good health." "As Selective Service has revealed," Mr. Wallace said, that "too large a proportion of our younger men now fall below reasonable health standards, this is a warning signal to America with respect to the state of health of all segments of our population. This condition calls for immediate and drastic

action. We must see that medical attention is available to all the people. But this health program must be achieved in the American way. All persons should have the right to go to the doctor and hospital of their own choosing. The federal and state governments should work hand in hand making health insurance an integral part of our Social Security program just as old age and unemployment benefits are today. We need more hospitals and doctors. We should make sure that such facilities are available and that we build hospitals in every community, rural and urban, that does not now have such facilities for all of its people. We must not be content to provide medical attention for people after they become sick. We must implement and extend our knowledge of maximum health as well as prevention of sickness. The government should appropriate needed funds to finance a greatly expanded program of medical research in private and public institutions."

Medical Legislation

MEDICAL BILLS IN CONGRESS

Bills Introduced.—S. 406, introduced by Senator Downey, California, provides for health programs for government employees and contemplates the utilization of osteopathic services in connection with any care to be provided government employees under the bill. H. R. 1666, introduced by Representative Rogers, Massachusetts, provides for the registration, selection and induction into the armed forces of qualified graduate female nurses. H. R. 1699, introduced by Representative Short, Missouri, proposes the establishment of an Optometry Corps in the Medical Department of the United States Army. H. R. 1688, introduced by Representative Davis, Tennessee, would authorize the President to appoint as commissioned officers in the Medical Corps of the Army and the Medical Corps of the Navy, on recommendation of the Surgeon General of the Army or the Navy, as the case may be, x-ray technicians who are regularly registered to practice as such in any state or the District of Columbia. H. R. 1661, introduced by Representative Rogers, Massachusetts, proposes the establishment of a permanent Veterans Medical and Hospital Corps in the Veterans Administration. This corps will consist, it is contemplated, of a Medical Corps, a Nurse Corps, a Corps of Laboratory Technicians, a Corps of Physical Therapists and Occupational Therapists, a Corps of Pharmacists, a Corps of Dietitians, a Corps of Librarians and a Corps of Social Workers. H. J. Res. 23, introduced by Representative Voorhis, California, proposes to establish the first week in October of each year as National Employ the Physically Handicapped Week. S. 143, introduced by Senator Thomas, Utah, provides that commissioned and warrant officers placed in St. Elizabeths Hospital or in certain United States Public Health Service hospitals shall be liable to pay such rate per day as may be prescribed by the President. H. R. 1764, introduced by Representative Chapman, Kentucky, proposes to amend the Insecticide Act of 1910 so as to provide that any white powder insecticide or fungicide containing arsenic in its elemental form or any of its combinations, or fluorine in any of its combinations, shall, unless deemed unnecessary by the Secretary of Agriculture for the protection of public health, be considered to be adulterated unless it is distinctly colored in accordance with regulations promulgated by the Secretary. H. R. 584, introduced by Representative Rogers, Massachusetts, provides that any World War ex-serviceman shown to have active pulmonary tuberculosis of a compensable degree shall be deemed to be totally disabled for purposes of compensation when hospitalized. H. R. 599, introduced by Representative Springer, Indiana, proposes to amend the existing law so as to prohibit the requirement of the taking of the so-called pauper's oath by certain applicants for hospital treatment or domiciliary care under veterans' laws. H. R. 592, introduced by Representative Spence, Kentucky, proposes to establish in the United States Public Health Service a division to promote water pollution control activities. S. 293, introduced by Senator Wagner, New York, for himself and Senator Wheeler, Montana, and H. R. 1102, introduced by Representative Jennings, Tennessee, propose to amend the Railroad Retirement Acts and the Railroad Unemployment Insur-

ance Act so as to provide, among other things, sickness and maternity benefits for employees. This legislation would authorize the administrative board to enter into agreements or arrangements with doctors, hospitals, clinics or other persons for securing the examination, physical, medical, mental or otherwise, of persons claiming, entitled to or receiving sickness or maternity benefits and the performance of services or the use of facilities in connection with the execution of the statements of sickness which must be filed by employees to obtain the benefits. H. R. 1658, introduced by Representative Philbin, Massachusetts, proposes to amend the Selective Training and Service Act so as to provide that medical statements be furnished, without request therefor, to persons discharged from the armed forces for disability. S. 200, introduced by Senator Russell, Georgia, provides for federal assistance in the maintenance, expansion and operation of school lunch and school milk programs. The bill would make available for the purposes indicated the sum of \$65,000,000 for the fiscal year ending June 30, 1945, and for each fiscal year thereafter such sums as may be necessary but not to exceed \$100,000,000 for any one fiscal year. H. R. 1209, introduced by Representative Walter, Pennsylvania, and H. R. 1108, introduced by Representative Abernethy, Mississippi, propose to establish uniform procedure relative to the proof of age or place of birth or of death. H. R. 1380, introduced by Representative Reed, New York, proposes to exempt certain religious, charitable, scientific, literary and educational organizations from the requirement of withholding tax at source on wages. H. R. 662, introduced by Representative Cannon, Florida, would amend the Social Security Act to authorize the payment of federal old age and survivors' insurance benefits to certain individuals who become permanently and totally disabled before attaining the age of 65. H. R. 1416, introduced by Representative Angell, Oregon, provides for the payment of annuities to blind persons. H. R. 313, introduced by Representative McMillan, South Carolina, provides for a uniform allowance for members of the Army Nurse Corps. H. R. 536, introduced by Representative Peterson, Florida, provides that a veteran's compensation, pension or retirement pay shall not be reduced during his hospitalization or domiciliary care.

DISTRICT OF COLUMBIA

Bills Introduced.—S. 125, introduced by Senator Bilbo, Mississippi, and H. R. 322, introduced by Representative Randolph, West Virginia, provide for the disposition of funds collected by the District of Columbia examining, licensing and other boards and commissions, including the Commission on Licensure to Practice the Healing Art. This legislation provides that fees and charges for licenses, permits, examinations, certificates and registrations shall be paid to the Collector of Taxes and by him deposited in the Treasury of the United States to the credit of the District of Columbia. H. R. 1625, introduced, by request, by Representative Randolph, West Virginia, provides for the abolition of the office of coroner and for the organization of the office of medical examiner for the District of Columbia.

STATE LEGISLATION

Massachusetts

Bills Introduced.—S. 273, to amend those provisions of the medical practice act relating to the limited licensing of interns and medical officers in hospitals maintained by the state or governmental subdivision, proposes also to permit such limited registration to a fellow and to interns, fellows or medical officers in private hospitals and in clinics. H. 372 proposes to establish a cash sickness compensation act to provide compensation for wage losses due to unemployment on account of sickness. H. 673 proposes to direct the department of public health to make an investigation and study relative to the decay of teeth resulting from a lack of fluorine.

Wyoming

Bill Introduced.—H. 47 proposes to authorize the state board of health to cooperate with the United States Public Health Service and the Children's Bureau in matters related to the prevention, treatment and control of diseases and to accept relevant grants which may be made by the United States, any of its agencies, or a private agency or foundation.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Changes in Health Officers.—Dr. Philip A. Bearg has been appointed health officer of San Luis Obispo County to succeed Dr. Harrison Eilers, who resigned to accept a similar position in Long Beach (*THE JOURNAL*, Nov. 25, 1944, p. 845). —Dr. William L. Denton, Bridgeport, has been named health officer of Mono County.

Physician Faces Imprisonment on Abortion Charge.—The San Francisco *Bulletin* recently reported that Charles Bacon Boudwin, Los Angeles, and his nurse, Mrs. Ella Berry, faced prison sentences of two to five years after they had been found guilty by a superior court jury of performing an abortion on a woman a year ago. Dr. Boudwin's license to practice medicine was revoked June 28, 1944 (*THE JOURNAL*, Aug. 19, 1944, p. 1153).

Changes in the Faculty at Stanford.—Among the recent changes on the staff of Stanford University School of Medicine, San Francisco, are the following:

Capt. Philip K. Gilman (MC), on leave of absence with the Navy, to clinical professor of surgery emeritus.

Dr. George W. Hartman to assistant clinical professor of surgery (genitourinary) emeritus.

Dr. Mary I. Preston to assistant clinical professor of pediatrics emeritus.

Dr. C. Frederic Fluhmann to associate clinical professor of obstetrics and gynecology.

The Musical Sons of Aesculapius.—Dr. Willard Lee Marmelszadt, intern at the Queen of Angels Hospital, Los Angeles, recently received the William Osler Medal of the American Association of the History of Medicine for a musical opus which has been deemed a noteworthy contribution to medical history. The work, entitled "The Musical Sons of Aesculapius," was begun while he was a student at Tulane University of Louisiana School of Medicine, New Orleans, where he graduated in 1944.

FLORIDA

Public Health Election.—Dr. Wieland W. Rogers, Jacksonville, was chosen president of the Florida Public Health Association at its recent annual meeting in Gainesville. Other officers included Dr. George A. Dame, Jacksonville, and Russell Broughman, sanitary engineer, Miami, vice presidents, and Dr. Edward M. L'Engle, Jacksonville, secretary-treasurer.

Personal.—Ross A. McFarland, Ph.D., medical coordinator of Pan American World Airways System, is in Miami conducting investigations in connection with alleviating crew and passenger fatigue on long range high altitude flights. Dr. McFarland, who is connected with the division of industrial research at Harvard Medical School, Boston, also is working on the control of insect borne infectious diseases by means of built in fumigating apparatus. —Dr. Herbert L. Bryans, Pensacola, was elected chairman of the Medical Advisory Committee of the State Rehabilitation Service at its organizational meeting held in Jacksonville recently. Other members of the committee are Drs. Frank L. Fort and Henry Hanson, Jacksonville; James L. Anderson, Miami, and Rollin D. Thompson, Orlando.

GEORGIA

Abner Calhoun Honored.—On December 21 the Fulton County Medical Society voted to name the Assembly Hall of the Academy of Medicine in memory of the late Dr. Abner Wellborn Calhoun, father of Dr. F. Phinizy Calhoun, Atlanta. The one hundredth birthday of Dr. Calhoun will be observed by Emory University School of Medicine in April with an ophthalmic seminar (*THE JOURNAL*, January 13, p. 110). The rededication of the assembly hall in honor of him will be a feature of the seminar.

ILLINOIS

New Chief of Tuberculosis Control.—Dr. Clifton F. Hall, Big Rapids, Mich., has been appointed chief of the division of tuberculosis control of the Illinois State Department of Public Health, effective January 15. Dr. Hall, who graduated at the University of Louisville School of Medicine in 1930 and the Harvard School of Public Health with a master in public health degree in 1938, has served five years

as director of the division of tuberculosis control of the Kansas State Board of Health and five years as health officer of the local bicounty health department that serves Mecosta and Osceola counties with headquarters at Big Rapids, Mich.

CHICAGO

Clinical Conference Canceled.—The Chicago Medical Society announces that its second annual clinical conference, scheduled to be held February 27-March 1 at the Palmer House, has been canceled.

Industrial Meeting.—The Chicago Society of Industrial Medicine and Surgery held its midwinter scientific meeting at the Palmer House, January 29. Dr. Vinton E. Siler, Cincinnati, spoke, among others, on "Infections of the Hand."

Personal.—Mr. Patrick H. Costello, secretary of the National Association of Boards of Pharmacy, 77 West Washington Street, Chicago 2, has been elected to fill the vacancy on the board of trustees of the United States Pharmacopeial Convention caused by the recent death of Evander F. Kelly, Ph.D. (*THE JOURNAL*, Nov. 11, 1944, p. 715). —Miss Evelyn G. Johnson on November 22 was appointed executive secretary of the Chicago Hospital Council.

Refresher Course in Otolaryngology.—The fifth semi-annual refresher course in laryngology, rhinology and otology will be conducted by the University of Illinois College of Medicine, March 26-31. While the course will be largely didactic, some clinical instruction will be included. This course is intended primarily for ear, nose and throat specialists. As the registration is limited to thirty, applications will be considered in the order in which they are received. The fee is \$50. When writing for application please give details concerning school and year of graduation, and past training and experience. Dr. Abraham R. Hollender is chairman of the Refresher Course Committee, Department of Otolaryngology, University of Illinois College of Medicine, 1853 West Polk Street, Chicago 12.

Advisory Council on Hematology Research.—A medical advisory council has been appointed for the Hematology Research Foundation to assist in the allocation of its funds and related medical problems. Members of the council include:

Dr. Raphael Isaacs, director of the hematology department, Michael Reese Hospital.

Dr. Louis R. Limarzi, assistant professor of medicine, University of Illinois College of Medicine.

Dr. Andrew C. Ivy, Nathan Smith Davis professor of physiology and pharmacology and head of the department, Northwestern University Medical School.

Dr. Ludvig Hektoen, emeritus professor of pathology (Rush) University of Chicago School of Medicine.

Dr. Anton J. Carlson, professor emeritus of physiology, University of Chicago School of Medicine.

Dr. Italo F. Volini, dean of Loyola University School of Medicine.

Dr. Otto Saphir, pathologist of Michael Reese Hospital.

The objective of the Hematology Research Foundation, which was organized in 1944 (*THE JOURNAL*, May 13, 1944, p. 159), is to seek a cure or successful treatment for pernicious anemia, Hodgkin's disease, leukemia and other blood disorders through scientific research. Officers of the foundation include Mrs. Phillip Marcus, president; Mrs. Joseph Reader, treasurer, and Mrs. Jack Hornstein, executive secretary.

IOWA

Outbreak of Trichinosis.—What was said to be the state's greatest outbreak of trichinosis in ten years was reported in Lowden, January 12. Forty-three residents of the Lowden community area ranging in age from 8 to 65 years were ill at the time of this report. No deaths had been recorded.

KANSAS

Bulletin Taken Over by Menninger Foundation.—The *Bulletin of the Menninger Clinic* in Topeka was recently taken over by the Menninger Foundation, a nonprofit organization to further psychiatric research, education and treatment. The board of editors will remain the same and the bulletin will continue to publish articles on psychiatry, psychosomatic medicine, psychology and related clinical fields.

Venereal Disease Central Registry.—Harry L. Hinson Jr., assistant sanitarian, U. S. Public Health Service Reserve, has been assigned to the division of venereal disease control, Kansas State Board of Health, Topeka, to set up and operate a venereal disease central registry. According to the *New York Letter*, all reported cases of venereal disease in the state will clear through the central registry and will be tabulated by Mr. Hinson.

The Hertzler Lecture.—Dr. Warren H. Cole, professor and head of the department of surgery, University of Illinois College of Medicine, Chicago, delivered the tenth annual lecture under the Arthur E. Hertzler Lectureship at the University of

Kansas School of Medicine January 10. His subject was "Chronic Cystic Mastitis." In 1935 Alpha Upsilon of Phi Beta Pi established the Arthur E. Hertzler Lectureship in honor of Dr. Hertzler, Halstead. The lectureship is entirely supported by contributions of current active members of the fraternity.

MICHIGAN

Institute of Nutrition.—A new service organization has been established at the Michigan State College of Agriculture and Applied Science, East Lansing, to be known as the Institute of Nutrition, *Science* reports. It is planned to coordinate and integrate instruction and research in nutrition and to bring together workers in the field. The program in research and teaching of the college has been broadened to include the production, processing and consumption of food by man and animal. The institute will supply a contact between industry and the college to further research in food and nutrition and will supply the food industry with results from the laboratory. It in no sense competes with or supplants the research of the experiment station but rather will supplement it through additional funds. An administrative committee of seven has been named, with Carl F. Huffman, Ph.D., research associate of dairying at the college, as chairman.

Annual Clinic Day.—Mount Carmel Mercy Hospital, Detroit, held its annual clinic day on January 31. Among the speakers were:

- Dr. Carl S. Ratigan, Dearborn, chief of staff.
- Dr. Roger V. Walker, president of the academy of surgery.
- Dr. Franklin H. Top, Recent Experiences in Treatment of Poliomyelitis.
- Dr. Elmer Hess, Erie, Pa., Hypertension from a Urologic Point of View.
- Dr. Thomas H. McGavack, New York, Thiouracil in the Management of Thyrotoxicosis.
- Dr. Ward F. Seeley, Hemorrhage of Late Pregnancy.
- Dr. Henry K. Ransom, Ann Arbor, Carcinoma of Large Intestine.
- Dr. Clement A. Smith, Diabetes in Children.
- Dr. Max Thorek, Chicago, History and Clinical Application of Tubal-vagular Gastrostomy.

Dr. Henry L. Smith was toastmaster at a luncheon meeting that was addressed by Dr. Leroy W. Hull, president, Wayne County Medical Society, Dr. Andrew S. Brunk, president of the state medical society, and Dr. Albert C. Furstenberg, Ann Arbor, on "Postwar Program for Medical Education." Dr. Edwin P. Jordan, Assistant Editor of *THE JOURNAL*, Chicago, addressed the evening dinner meeting at the Dearborn Inn on "Status of Medicine Today in Regard to Federal Control."

MINNESOTA

The Elias Potter Lyon Lecture.—On January 18 William C. Rose, Ph.D., professor of biochemistry, University of Illinois, Urbana, Ill., delivered the Elias Potter Lyon Lecture at the University of Minnesota Medical School, Minneapolis. His subject was "The Amino Acid Requirements of Man."

New Lectureships Created at Minnesota.—The J. B. Johnston lectureship in neurology has been created at the University of Minnesota Medical School, Minneapolis, from a gift from Dr. Johnston's widow, Mrs. J. B. Johnston, Los Altos, Calif. The lectureship is named to honor John B. Johnston, Ph.D., who served as professor of comparative neurology in the medical school from 1908 to 1915 and dean of the College of Science, Literature and the Arts from 1914 to 1937. It is planned to invite to the medical school annually a prominent neurologist to present the lecture. Announcement is also made of the new Leo G. Rigler lectureship in radiology endowed at the medical school by a group of friends and colleagues of Dr. Rigler, professor and head of the department of radiology, in recognition of his contributions to the teaching and practice of medicine, particularly in the field of radiology.

Another Citizens Aid Gift for Cancer.—In the recent final distribution of the assets of the Citizens Aid Society, Minneapolis, the trustees set aside funds totaling about \$16,000 to complete several research projects of the University of Minnesota Medical School, Minneapolis, which they had agreed to support. In addition the trustees set up a fund to provide \$12,000 annually for a period of ten years for the support of the Cancer Institute at the university. The Citizens Aid Society has for thirty years been supporting various cultural, educational and welfare activities in Minneapolis. Cancer has been one of the special interests of the society since 1924, when the trustees provided funds to construct the Cancer Institute addition to the University Hospital. The institute is a memorial to Mr. George Chase Christian, the son of Mr. Henry Christian, who established and endowed the Citizens Aid Society. Mrs. George Chase Christian is president.

MISSOURI

Personal.—Dr. Harriet H. S. Cory, St. Louis, executive director of the Missouri Social Hygiene Association, is visiting Puerto Rico, Cuba, Haiti and the Virgin Islands as a representative of the American Social Hygiene Association, assisting Kenneth Miller, Caribbean representative, in the organization of several local hygiene associations for the prevention of social diseases, according to the Pan American World Airways.

Medical School Addition.—St. Louis University School of Medicine, St. Louis, plans a \$500,000 addition to its \$2,600,000 postwar expansion program. Plans have been completed and work will be started on the medical school immediately on release of permission by the War Production Board, according to the *Journal of the Missouri State Medical Association*. The building will be four stories of brick and stone and will contain an amphitheater with accommodations for the entire student body.

Portrait of Hal Foster.—The Kansas City Society of Ophthalmology and Oto-Laryngology will present an oil painting of Dr. Hal L. Foster, Kansas City, to the American Academy of Ophthalmology and Otolaryngology. The presentation is to take place during the 1945 session of the academy, when the group will observe its fiftieth anniversary, provided the meeting is held. The national organization was founded by Dr. Foster at a meeting in Kansas City in April 1896. He held the office of secretary from 1896 through 1898 and became vice president in 1920. As it is planned to exhibit the picture at each annual meeting, it will be placed where it will be a reminder to the academy members of the man who founded the organization. At the 1944 annual session of the academy Dr. Foster was elected to the Honor Section.

NEW YORK

Hospital News.—Under the will of Mrs. K. B. Hofheinz, Rochester, the Rochester General Hospital, Rochester, will receive a bequest of \$8,000 for the children's department.

Personal.—Dr. Joseph H. Beattie, who has been practicing in the Greenburgh vicinity for forty years, was guest of honor at a dinner given by the medical staff of the Dobbs Ferry Hospital, Dobbs Ferry, of which he is a former president.

New York City

Work on Osteomyelitis with Penicillin.—The Hospital for Joint Diseases is conducting a special study on the treatment of acute and chronic osteomyelitis patients with penicillin. Physicians are requested to refer such patients to the hospital.

The Harvey Lecture.—George Wells Beadle, Ph.D., professor of biology, Stanford University, Calif., will deliver the fifth Harvey Society Lecture of the current series at the New York Academy of Medicine, February 15. His subject will be "The Genetic Control of Biochemical Reactions."

The Williams Assistantships in Obstetrics and Gynecology.—The Rockefeller Foundation has given a grant to Cornell University Medical College and the New York Hospital to establish the J. Whitridge Williams Assistantships in obstetrics and gynecology. The positions are specifically designed for postwar training of a selective group that military service has deprived of advanced training comparable to that possible in the prewar period, according to *Science*.

Hospital News.—Work has begun on an expansion program at the New York Hospital to increase the number of beds from 977 to 1,138. Material and equipment priorities were granted by the War Production Board, and work is to be completed by the middle of the summer. The program will cost about \$600,000 but will not require the construction of any new unit. A formerly unused floor will be developed for use, and other sections of the building will be altered and rearranged.

The Biggs Memorial Lecture.—Fred C. Bishopp, Ph.D., assistant chief in charge of research, bureau of entomology and plant quarantine, U. S. Department of Agriculture, Washington, D. C., will deliver the annual Hermann M. Biggs Memorial Lecture at the New York Academy of Medicine April 5. The lecture, which is under the auspices of the committee on public health relations of the academy, will be on "Medical and Public Health Importance of the Insecticide DDT."

Society Receives Gift.—At the meeting of the Medical Society of the County of Kings, December 19, Mrs. James M. Kingsley, Boonton, N. J., niece of the late Dr. Joseph H. Hunt, presented to the society the silver trowel used at the

cornerstone laying of the society building on Nov. 10, 1898. This trowel was used by Dr. Hunt, then president of the society. Mrs. Kingsley also gave the society the silver mounted gavel presented to Dr. Hunt, as president, at the 79th annual meeting, held Jan. 15, 1900.

Convicted for Abortion.—Dr. Charles Victor Dukoff was sentenced on December 15 to serve from two to four years in Sing Sing on each of five counts charging him with performing abortions and for which he had been convicted a week earlier. The sentences are to run concurrently. The physician was said to be indicted after a raid on his office last January, after which he was charged with the conduct of a "wholesale" abortion practice. It was said that he had received from \$150 to \$250 for each abortion.

Diagnostic Service for Tropical Diseases.—The New York City Department of Health has established a tropical disease diagnostic service which provides both laboratory and clinical facilities and has the advice and assistance of the specialists on the tropical disease staff of the DeLamar Institute of Public Health, Columbia University. Dr. Wheelan D. Sutliff, assistant director of the bureau of laboratories, is in charge of the laboratory work, and Dr. Howard B. Shookhoff of the bureau of preventable diseases is in charge of the epidemiology aspects. The address of the tropical disease diagnostic service is 600 West 168th Street, Room 704, New York 32.

OHIO

Personal.—Dr. Alice M. Bustin, Columbus, has been appointed medical member of the state board of cosmetology for a term ending Nov. 1, 1947. She succeeds Major Thomas D. Santurello, M. C., who has been in the medical corps of the army for more than two years.

Commonwealth Grant for Work on Chemical Factors in Disease.—The Commonwealth Fund of New York has allocated \$32,600 to assist Enrique E. Ecker, Ph.D., professor of immunology, Western Reserve University School of Medicine, Cleveland, and the Institute of Pathology, to continue his work for two more years on the "chemical factors involved in the resistance to disease." The grant will enable Dr. Ecker to add a physical chemist to his staff.

Faculty Appointments at Ohio University.—Dr. George H. Ruggy, assistant professor of physiologic chemistry and pharmacology, has been appointed to the new position of junior dean in the Ohio State University College of Medicine, Columbus. Dr. Bruce K. Wiseman has been appointed chairman of the department of medicine, succeeding Dr. Charles A. Doan, who was recently named dean of the medical school (THE JOURNAL, Dec. 16, 1944, p. 1041). Dr. Ruggy graduated at the University of Chicago School of Medicine in 1940 and has been a member of the staff of Ohio State since 1932, serving successively as graduate assistant, instructor and assistant professor except while he was at the University of Chicago and the year 1940-1941, when he was house officer at Blodgett Memorial Hospital, Grand Rapids, Mich. Dr. Wiseman graduated at the Indiana University School of Medicine, Indianapolis, in 1928; he has been a member of the Ohio staff since 1930, serving first as assistant professor of medical research. In 1936 he was named associate professor and in 1939 professor.

PENNSYLVANIA

Pittsburgh

Course in Slit Lamp Microscopy.—The committee on graduate education of the Allegheny County Medical Society is offering a course in slit lamp microscopy of the living eye, combined with a course in glaucoma surgery. Instruction will be by the department of ophthalmology of the Montefiore Hospital under the direction of Dr. Harvey E. Thorpe and his associates. The course will begin February 12 and run for three consecutive days. Information may be obtained from the committee on graduate education, Allegheny County Medical Society, 5092 Jenkins Arcade Building, Pittsburgh 22.

TEXAS

Grants to University.—The John and Mary R. Markle Foundation of New York has given a grant of \$2,500 to support the work of Eric Ogden, B.Sc., professor of physiology, University of Texas Medical Branch, Galveston, on blood flow and hypertension and a grant of \$3,300 for the support of studies on filariasis to be made by J. Allen Scott, Sc.D., associate professor of epidemiology and preventive medicine at the university.

Clinical Significance of Rh Factors.—A conference on the clinical significance of Rh factors will be held at the University of Texas Medical Branch, Galveston, February 9-10. The conference has been called at the suggestion of laboratory workers and Texas military hospitals. It will be under the general direction of John G. Sinclair, Ph.D., professor of anatomy, and Dr. Henry H. Sweets Jr., director of the John Sealy Clinical Laboratories.

WASHINGTON

Recommendations for Medical School.—The present legislature has been asked to appropriate \$450,000 to maintain the proposed school of medicine and dentistry at the University of Washington, Seattle. This sum, it is expected, would maintain the school for two years. At ensuing sessions of the legislature it is hoped to obtain additional appropriation of \$3,700,000 for maintenance and improvement. The Washington State Medical Association is sponsoring this project, which would consist of a standard four year course of instruction in medicine and dentistry. The present buildings, laboratory, library and other facilities of the university will allow the accommodation of 50 students in medicine and 50 in dentistry in the school year of 1946 if funds, largely for faculty salaries, are made available now. The project has been under consideration for a long period by committees of the state association in conjunction with the board of regents and the president of the university (THE JOURNAL, July 1, 1944, p. 666; December 2, p. 907).

State Health Department Reorganized.—Dr. Arthur I. Ringle, who has been serving in full time public health work in local health departments in Washington for a number of years, has been appointed director of the state department of health, Seattle. The position has been filled by Dr. John A. Kahl, assistant health director since Dr. Leland E. Powers was called to active duty by the U. S. Public Health Service on Dec. 15, 1944, for assignment to the United States Relief and Rehabilitation Administration. The state department of health has been reorganized into four functional divisions: division of preventive medical services, in charge of Dr. John L. Jones with the title of chief; the division of central administration, in charge of Dr. Ringle as state director of health; the division of public health engineering, with M. S. Campbell, C.E. serving as chief, and the division of local health services, with Dr. Kahl serving as chief of the division and assistant state director of health. The division of preventive medical services includes the communicable disease control section, in charge of Dr. Austin U. Simpson; the maternal and child hygiene and crippled children's section, in charge of Dr. Jones as acting head; the industrial and adult hygiene section, with Dr. Lloyd M. Farner as head; the mental hygiene section, a newly created unit, with Dr. George C. Stevens in charge (THE JOURNAL, Dec. 2, 1944, p. 907), and the dental hygiene section, with Francis I. Livingston, D.D.S., in charge. Dr. Ringle graduated at University of Colorado School of Medicine, Denver, in 1935.

WEST VIRGINIA

Personal.—Dr. Charles N. Scott, who has been serving as plant physician for the American Viscose Company at Nitro, has resigned to enter the Navy. Dr. John F. Cadden, who has been serving on the Viscose medical staff, with headquarters at Wilmington, Del., has been named acting plant physician.—Dr. Joseph P. Webb, instructor in medicine and research fellow in aviation medicine at the University of Cincinnati College of Medicine, has been appointed internist and medical director of the Chesapeake and Ohio Hospital, Huntington.

GENERAL

Conference on Medical Service Canceled.—The National Conference on Medical Service, scheduled to be held February 11 in Chicago, has been canceled in compliance with a request received from the Office of Defense Transportation.

Cancer Society Changes Address.—The American Cancer Society announces that its new address is 350 Fifth Avenue, Room 1211, New York 1. The new executive council of the society, under the chairmanship of Eric A. Johnston, plans to conduct a campaign to raise \$5,000,000 for research.

Journal of Clinical Psychopathology.—The Association for the Advancement of Psychotherapy announces that its official organ is the *Journal of Clinical Psychopathology and Psychotherapy*, formerly *Journal of Criminal Psychopathology*. The chief editor of the journal is Dr. Vernon C. Branham, Box 631, Monticello, N. Y. Dr. Emil A. Gutheil, 16 West 77th Street, New York 24, is secretary-treasurer of the association.

Special Society Elections.—Recently elected officers of the Central Neuropsychiatric Association include Drs Abram C Bennett, Omaha, president, Edwin Rogers Smith, Indianapolis, vice president, and William C Menninger, Topeka, Kan., secretary-treasurer.—Dr Walter A Sternberg, Mount Pleasant, Iowa, was named president-elect of the Mississippi Valley Medical Society recently and Dr Grayson L Carroll, St Louis, was installed as president. Other officers include Drs Louis H Jorstad, St Louis, Elmer E Nyström, Peoria, Ill., and Ernest J Lessenger, New London, Iowa, vice presidents and Harold Swanberg, Quincy, Ill., secretary-treasurer.

Society for the Study of Sterility Formed.—The recent organization of the American Society for the Study of Sterility has been announced with Drs Walter W Williams, Ithaca, N Y, chairman, and John O Haman, 490 Post Street, San Francisco 2, secretary-treasurer. These two physicians, with the following, constitute the board of directors: Drs Edwin C Hamblen, Durham, N C, Lewis Michelson, San Francisco, Abner I Weisman, New York, Lyman W Mason, Denver, and Edwin M Robertson, Kingston, Ont. The objectives of the society are:

The encouragement of scientific investigation of fertility and infertility.
The improvement of the diagnosis and treatment of infertility.
The correlation and dissemination of the information obtained from these studies.

Foundation for Mentally Abnormal Children.—The authorities of the state of New York have accepted the filing of the certificate of incorporation of a new national child care organization to be known as the Foundation for Child Care and Nervous Child Help, Inc., which will start its activities in the near future. The general purpose of the foundation is the advance of work to help mentally sick children. Research projects will be started and supported and various publications undertaken. President of the board of directors of the new foundation is Dr Leo Kanner of Johns Hopkins University School of Medicine, Baltimore. Ernest Harms, editor of the journal *The Nervous Child*, New York, is executive director. The foundation has its office at 30 West 58th Street, New York 19. As a major task the foundation intends to create a public school of exceptional children in New York, developed in such a way that it can be used as a sample for similar institutions in other cities. There is also planned an institution for the treatment of prepsychotic and predelinquent children. Connected with both institutions will be a training school for nurses, teachers and social workers for the care of subnormal children.

Awards for Work in Fertility of Human Beings.—John MacLeod, Ph.D., research associate in anatomy, Cornell University Medical College, New York, received a cash award of \$500 during the twenty-fourth annual meeting of the Planned Parenthood Federation of America at the Waldorf-Astoria New York, January 24. The award was made possible by the Albert and Mary Woodard Lasker Foundation for his scientific research in the motility of human sperm cells. In simple terms Dr MacLeod has determined not only what factors cause the sperm cells to travel at the rate of about a quarter of an inch in two minutes in a congenial medium but the substance which may increase or decrease this activity. Because of this discovery it may be possible after further research to speed up or slow down the rate of speed of sperm cells, the former invaluable in the correction of infertility, the latter in the control of fertility. Honorable mentions went to Dr Samuel L Siegler, Brooklyn, for his volume on "Human Fertility in the Female" and to Dr Robert S Hotchkiss, New York, for his volume on "Human Fertility in the Male." Dr Felix J Underwood, executive officer, Mississippi State Board of Health, Jackson, will receive a second \$500 award for his state's achievement in including planned parenthood services as an integral part of its public health programs of maternal care. This action on the part of the Mississippi health department in 1944, under the direction of Dr Underwood, brings to six the number of states officially making planned parenthood a normal part of their public health program.

Narcotic Violations.—The Bureau of Narcotics, Treasury Department, Washington, D C, reports the following narcotic violations and the action indicated:

Dr Brady H Hughes, Birmingham, Ala., pleaded nolo contendere, Oct 25, 1944, to a charge of falsely making narcotic prescriptions, placed on probation for one year.
Dr Lyman W Gay, Lord formerly of Baltimore and of Bridgeport, Conn., and recently located in Newark, N J, was convicted in the state court of Connecticut April 13, 1944, of violation of the state narcotic law sentence of one year in jail suspended.
Dr Stephen A Peters Jr., Gainesville, Ga., pleaded guilty Oct 23, 1944, to violation of the federal narcotic law, sentenced Oct 27, 1944, to a term of fifteen months.
Dr Frank Morse Nichols, Warsaw and La Grange, Ind., pleaded guilty Nov 3, 1944, to a violation of the federal narcotic law, placed on probation for one year.

Dr Fred A Stahl, Springfield, Mo., convicted of violation in the U S District Court at Springfield, of narcotic laws, Jan 28, 1944, and sentenced to serve a term of two years. In October the circuit court of appeals for the eighth circuit affirmed the decision of the lower court, which had been appealed by the physician.

Dr Guy S Bryan, Silver City, Miss., pleaded guilty in the U S District Court, Jackson, Miss., May 8, 1944, to violation of false execution of narcotic prescriptions, sentenced to serve a term of eighteen months.

Dr D Duane Parrish, East Syracuse, N Y, received on April 13, 1944, a suspended sentence of six months following his plea of guilty to a violation of the federal narcotic laws, placed on probation for two years with the understanding that he would not deal in narcotics during that time.

Dr Linwood H Justis, Littleton, N C, sentenced to a term of one year and one day, effective Oct 16, 1944, for violation of the federal narcotic laws.

Dr John A Bentley, Allen, Okla., received a suspended sentence of six months on Oct 2, 1944 following a plea of guilty to violation of federal narcotic laws, placed on probation for five years.

Dr Raymond A Thompson, Pittsburgh, pleaded guilty in Erie Pa., May 23, 1944, to violation of the federal narcotic law and was sentenced to imprisonment for a term of two years.

Dr John Jacob Dommick, Prosperity, S C, pleaded guilty to violation of the federal narcotic law May 8, 1944 and was sentenced to a term of nine months in prison or to pay a fine of \$500, the fine was paid.

Dr Wendell Cotton, Rock Springs, Wyo., pleaded guilty at Cheyenne Wyo. on May 22, 1944, to violation of the federal narcotic law and was sentenced to imprisonment for three years.

CORRECTION

Shortage of Nurses.—The editorial in *THE JOURNAL*, January 6, referring to the shortage of nurses stated that the number of nurses now on duty was 47,478. This figure is in error, since the total number of nurses on duty with the Army is 42,000.

Government Services

Appointments of Medical Officers in Public Health Service

A limited number of appointments of medical officers in the Regular Corps of the U S Public Health Service will be made in grades above senior assistant surgeon (captain). Applicants must be citizens of the United States, must have been graduated from a recognized medical school and must have had at least twelve years of professional experience since graduation from medical school. The examination will consist of an evaluation of information furnished on application forms and questionnaires supplied by the Surgeon General at the request of the applicant, a report of physical examination by Public Health Service medical officers and a written professional examination in practice of medicine, practice of surgery, public health, and a thesis on a subject selected by the applicant. Candidates will be rated competitively. Applications must be made before March 1. Written examination will be held on March 8 and 9 at places approved by the Surgeon General.

Bill to Create Research Institute in Public Health Service

Hon James E. Murray, U S Senator from Montana, on January 10 introduced a bill to establish a National Institute of Dental Research and to aid and encourage dental studies that will advance the prevention and treatment of dental diseases. It is proposed that the institute be established as a division of the National Institute of Health in the U S Public Health Service, an arrangement which would foster the development of dental research that is already being done by the public health service and other agencies, public or private, according to a statement of Senator Murray discussing the bill. If enacted, the Surgeon General of the Public Health Service would direct the new institute in its work with the assistance of a national advisory dental research council to include, in addition to the Surgeon General as chairman, six appointed members, at least four of whom shall be dentists. The institute would conduct and aid research on the cause, prevention and methods of diagnosis and treatment of dental diseases and conditions, promote coordination of dental research, provide fellowships in the institute and make grants-in-aid to universities and other institutions, secure the consultation services of other experts and cooperate with state health agencies. The bill proposes that Congress should authorize appropriations, up to a maximum of \$1,000,000, to erect and equip a suitable building after the war, and up to a maximum of \$730,000 a year to provide a budget to carry out the program. The institute would also be authorized to receive gifts from private sources.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Jan. 6, 1945.

Plan for Decentralizing London's Population

The unplanned growth of the largest city in the world has involved great evils. Between the two wars the population of greater London increased from 8,500,000 to 10,000,000. There was an orgy of house building, and new industries sprang up on sites unrelated to the shifting homes of the people. The average man of the new suburban housing estates travels 16 miles a day, at an annual cost of \$60, to get to and from his work. London's uncontrolled expansion became a scamper over the adjacent counties which produced little more than a jumble of building, services and transportation facilities, involving a waste of social capital, productive effort and human health and strength, overrunning valuable farm land, open spaces and beauty spots and enlarging the wilderness of stone and brick in which men live in juxtaposition but not in community. This intolerable process could easily continue when building is resumed after the war. But damage due to bombing from the air has given an opportunity for planning the reconstruction of outer London; under government orders, an important plan has been drawn up by Professor Abercrombie.

The main aim is to discourage the further growth of population and industry in the London region and to provide for their better distribution. The magnitude of the task is shown by the fact that over a million persons are involved in the transfer. This decentralization of population is only one part of the problem. The conservation of good agricultural land and the preservation of the green belt of outer London are examined also. The area dealt with amounts to 2,717 square miles. The green belt is to provide primarily for the recreation of Londoners, and only small population increases in the towns which it contains are to be allowed. Outside this is the "outer country ring," which contains distinct urban communities situated in land otherwise open and mainly agricultural. Here will be the principal reception area for the decentralized population. Additions will be made to the existing towns, and eight new towns, with a maximum population of 60,000 each, are to be established. The plan also proposes improvements in London's road system. Our roads are reputed to carry the densest traffic in the world, with an appalling toll of deaths. The need for traveling could be diminished by locating workers near their places of work. At present there is no such arrangement.

First Woman Professor at Oxford an Ophthalmologist

Dr. Ida Mann, well known for her researches in embryology of the eye, has had the title of professor conferred on her by Oxford University as long as she remains Margaret Ogilvie's reader in ophthalmology. She will receive a salary of \$10,000 as long as she refrains from private practice. This is the first time that a woman has been raised to the position of professor at Oxford. The appointment marks an important stage in the progress of the scheme for which the university has been collecting funds. Already \$500,000 has been raised of the \$1,250,000 required. The scheme is for research in the fundamental problems of vision, particularly biochemical problems.

Honor for Sir Thomas Lewis

The presidents of the Royal Society and the Royal College of Physicians have awarded the Conway Evans prize to Sir Thomas Lewis for his great contribution to our knowledge of the normal and abnormal mechanisms of the heart and

circulation. The prize, in accordance with the will of the late Dr. Conway Evans, is awarded for noteworthy scientific work. It has previously been awarded to physiologists—first to Sir Charles Sherrington in 1927, then to J. S. Haldane in 1929, and also to Sir Gowland Hopkins in 1938. The infrequency of the award indicates the importance of the work for which the prize is given. Unlike the previous recipients, Sir Thomas Lewis has worked in a field which he calls "clinical science" and which may be described as the application of scientific advances to clinical problems.

An Eminent Medical Centenarian

Sir Thomas Barlow, known best for his description of infantile scurvy ("Barlow's disease"), has attained the age of 100. He makes his annual Christmas appeal as president of the Royal Medical Benevolent Fund.

AUSTRALIA

(From Our Regular Correspondent)

Nov. 4, 1944.

Medical Research in Australia

For many years there has been growing criticism of the failure of the National Health and Medical Research Council in Australia to foster medical research. There are two reasons for this. The first is the limitation of funds, which are only £30,000 a year, and the second is the composition of the council, made up of men eminent in the field of health administration. Only one of the members could be described as a research scientist. This criticism was voiced at the time the council was originally formed, when it took over the duties of the Federal Health Council. Invidious comparisons are being made between the Australian Council for Scientific and Industrial Research and the National Health and Medical Research Council. The former is guided by a body composed of men eminent in research. The many fields in which it has functioned have amply demonstrated during the war the benefits of the scientific caliber of its composition.

A thoughtful contribution to the problem has been made by J. V. Connolly in "Some Australians Take Stock," published by Longmans, Green & Co. The usual story is that a university graduate visits overseas countries in order to gain experience and to meet other scientists eminent in his field. When such men are asked subsequently why they do not return to Australia, the usual answer is "The facilities there are not good enough." It is felt that brains and scientific ability are not among the commodities we can afford to export. Inevitably there will be among English speaking countries some interchange of people possessing special qualifications. Indeed, in many cases the migrant has adapted his training so effectively to the environment of his adopted country that he has been able to contribute noticeably to its development, but in the present instance the exodus is not part of a natural interchange and really constitutes an undesirable and avoidable loss.

A study of the ultimate settling place of the Rhodes scholars of Australia reveals that of those who were selected prior to 1927 more than half the graduates in medicine are now residing outside Australia. The example taken from the movement of Rhodes scholars has its parallel in the considerable number of Australians who have gone abroad without any of the inducements provided by scholarship awards. More than two hundred graduates from the Australia university alone are more or less permanently settled in England at the present time. Tuition in Australia is satisfactory. Technical education in the various schools is of an extremely high standard, although general education is possibly less so. The tendency for graduates to go abroad is welcomed, but the trouble is that too many of them remain abroad, and the net result is that Australia loses an influence that she can ill afford to be without.

A study of the wider field of medical practice in Australia seems justified to see if some light can be thrown on this problem. The first question that might be asked is "Is the medical profession in Australia overcrowded?" There is 0.74 medical graduate per thousand of population in Australia. This can be compared with England, where the figure is 0.85 per thousand. The factor of distance should be remembered when considering the percentage of medical graduates in Australia, since there is not the same concentration of population that one finds in other countries. Bearing this geographic factor in mind, it is fair to say that Australia is far from being oversupplied with medical practitioners. And yet, in spite of the apparently uncrowded field in Australia, a considerable number of Australian surgeons were practicing abroad before the war, and it seems that the surgeon particularly is the one who is most anxious to leave Australia to practice overseas. One reason for this might be found in the high standard of training possessed by the medical graduate who takes up a small country practice in one of the Australian towns. It is the normal thing for him to do his own surgical work and to do it competently. Thus consulting surgeons in the city receive nothing like the same amount of general surgery that is sent to the surgeon, say, in England, where the general practitioner practices almost exclusively as a physician. Fees in Australia do not always compare favorably with those obtained by consulting surgeons abroad. There is a great disparity between the income of a leading surgeon in Sydney or Melbourne and the income of his counterpart in, say, London or New York. Also there seems to be reluctance in Australia to give to the man who has moved to the top of the profession the formal recognition that is accorded to him elsewhere, although this reluctance is not confined to medicine. One might sum up by saying that the Australian surgeon has less opportunity at home than he is able to find abroad, while men working as general practitioners, doing their own surgery, can make a much greater income than they would in most overseas practices. In Australia all the influences affecting the standards of the profession and other specialized occupations tend toward the production of a fairly uniform level. There is little encouragement of special aptitude and no particularly high reward for ambition. This insistence on uniformity is only a manifestation of the philosophy which pervades not only the national economy but the whole social fabric of the country. If the approximation of Jack to the same plane as his master does contribute to the well being of the majority, it also limits the upper level of achievement and in so doing contributes to the exodus of those who consider that their talents will be better rewarded abroad.

A study of the social background against which Australians live can throw some light on this problem. It is true that the average Australian working man is a good deal better off than his counterpart in almost any other community. But for the more highly educated man the position is somewhat different. A certain impatience with nonconformity and a noticeable tendency toward materialism seem to be the products of our social evolution. These things militate against the development of any national culture. Attention to this problem has been revived recently as an aftermath of the visit of Sir Howard Florey of Oxford University, co-discoverer of penicillin and now professor of bacteriology at the University of Oxford. It is significant that Sir Howard was a graduate of the University of Adelaide. He drew attention to the fact that Australian universities turned out well equipped young men with a flair for research, yet these men had to seek overseas fields for their work because the facilities in Australia were not good enough. The main difficulty, he felt, was that professors and others were overburdened with teaching and a good deal of outside work. They had no time to pursue research, and without research universities were lowered to the level of technical schools. Oxford University receives an

annual government grant of something like £100,000 a year, and the Medical Research Council of Great Britain, subsidized by the state, had been able to undertake valuable research into war medical problems, Sir Howard said. This Council is controlled by scientists and protected from direct political interference. It is unfortunate that scientists, although strong in brain power, are weak in voting power. The result is that ministers of the government have a habit of expressing fervid agreement with their views and doing nothing.

The Australian Optical Industry

At the outbreak of war Australia had only a rudimentary munitions industry, which did not include the manufacture in quantity of precision optical instruments. This task was assigned by the Ministry of Munitions to the Ordnance Production Directorate, and a munitions optical panel was set up under the chairmanship of Professor T. H. Laby of Melbourne University. The first problem was the manufacture of optical glass, and commercial firms engaged in its production showed a reluctance to make available the necessary details and technic. Information, however, was freely offered by American scientists, and the production of optical glass in quantity was followed by the successful production of many types of optical munitions—telescopes, range finders, gun sights, directors, periscopes, stereoscopes and other material. Some of these products were of British design, and some have been optically and mechanically designed in Australia. Australian made lenses and prisms exported to the United States were not only part of reverse lend lease but were a recompense for the original information so willingly supplied by the United States. About one in four Australians wears spectacles, according to War Organization of Industry officials, who have been investigating the manufacture of Australian spectacles. The output of spectacle frames in the commonwealth is steadily rising, but lenses are still being imported in small quantities. It is hoped that an Australian firm formerly engaged in making gun sights and range finders will be able to produce all the lenses necessary for the new Australian spectacle industry.

Australian Record for a Blood Donor

Mr. W. J. Murphy, secretary of the South Australian Blood Transfusion Service, seems to have a claim for the record as a blood donor in Australia. In nine years he has given eighty-three blood transfusions totaling about 100 pints. He has given two donations in the same day and on another occasion gave three in two weeks. As a result of the latter his hemoglobin was reduced to 75 per cent, but in three weeks it returned to 95 per cent. Blood has always been taken by the needle method, and at no time has his vein been cut down on. He is 42 years of age and weighs nearly 13 stone (83 Kg.). He has never displayed any reaction to the procedure, and his statements are endorsed by the medical registrar of the Royal Adelaide Hospital, South Australia.

Marriages

LEON JAIR TAUBENHAUS, College Station, Texas, to Miss Marjorie Vera Polon in New York, November 18.

WILLIAM ROSS BUTTRAM JR., Chattanooga, Tenn., to Miss Augusta Lee Rees of Columbus, Ga., October 28.

PATRICK M. BERZITO, Mayfield, Pa., to Miss Dolores Margaret Johnson of Milwaukee, October 24.

FRANK R. STEELSMITH to Miss Julia E. Cockburn, both of Des Moines, November 1.

JAMES F. LEMMON to Miss Betty Neva Shrimmer, both of Akron, Ohio, October 12.

EDWARD KEZUR, Toledo, Ohio, to Miss Isabel Schechter of New York, October 29.

LEONARD V. GRATKINS to Miss Mabel Johnson, both of Chicago, November 16.

Deaths

Henry Greenwood Bugbee * New York; Columbia University College of Physicians and Surgeons, New York, 1903; chairman of the Section on Urology of the American Medical Association, 1922-1923; founder member of the American Board of Urology; member, past president and secretary of the American Association of Genito-Urinary Surgeons, which in 1944 awarded him the Keyes Memorial Medal for his contributions to urology; member and past president of the American Urological Association; past president of the New York Urological Association; past president and secretary of the Clinical Society of Genito-Urinary Surgeons; served as president of the International Urological Association; fellow of the American College of Surgeons and the New York Academy of Medicine; member of the Quiz Medical Society, the Royal Medical Society of Budapest and the Société d'Urologie Française; member and past president of the alumni of St. Luke's Hospital, where he had interned from 1903 to 1906, retired Jan. 1, 1945 as director of urology and remained on the staff as consulting urologist; surgeon-in-chief Vassar Brothers Hospital, Poughkeepsie, N. Y., from 1906 to 1910 and later consulting urologist; served as urologist and president of the medical board at the Lawrence Hospital, Bronxville, and the Woman's Hospital; consulting urologist at the Mountainside Hospital, Montclair, N. J., Muhlenberg Hospital, Plainfield, N. J., and the Mather Memorial Hospital, Port Jefferson, N. Y.; author of numerous articles on urologic subjects, and a section in Lewis's Surgery; served on the board of editors of the *Journal of Urology*; died January 17, aged 63.

William Henry Keleher * Woburn, Mass.; Harvard Medical School, Boston, 1892; president of the Middlesex East District Medical Society in 1913; formerly medical examiner of the fourth Middlesex district; president of the board of trustees of the Woburn Public Library; a director of the Woburn Cooperative Bank; chairman of the city board of health; school physician at St. Charles Parochial School; on the courtesy staff of the Winchester Hospital, Winchester, and on the staff of the Charles Choate Memorial Hospital; died December 4, aged 75, of carcinoma of the rectosigmoid.

William Abel Alton, La Mesa, Calif.; Lincoln (Neb.) Medical College of Cotner University, 1897; served during World War I; died in the Paradise Valley Sanitarium and Hospital, National City, November 16, aged 70, of bronchopneumonia following an operation for intestinal obstruction.

Glenn Andrews, Montgomery, Ala.; University of the City of New York Medical Department, New York, 1886; member of the American Medical Association; formerly member of the state board of censors; for eighteen years state prison inspector; died December 9, aged 82, of tuberculosis.

John Dean Boylan * Milford Center, Ohio; Western Reserve University School of Medicine, Cleveland, 1916; past president, vice president and secretary of the Union County Medical Society; member of the Radiological Society of North America, Inc.; served overseas during World War I; formerly health officer of Mahoning and Union counties; died November 19, aged 54, of cerebral hemorrhage.

John Arthur Bundy, Hill City, Kan.; University Medical College of Kansas City, Mo., 1906; died November 26, aged 66, of coronary occlusion.

Edward P. Christensen * Two Harbors, Minn.; Rush Medical College, Chicago, 1906; served as city and county health officer; medical superintendent and part owner of the Two Harbors Hospital; formerly member of the city council; first president of the Rotary Club; died November 10, aged 64, of coronary thrombosis.

John Alexander Clarke * Greenwich, Conn.; Bellevue Hospital Medical College, New York, 1897; for many years medical examiner for Greenwich; school physician; on the staff of Greenwich Hospital, where he died November 23, aged 73, of Addison's disease.

Edward Ellison Coburn, Columbus, Ohio; Starling Medical College, Columbus, 1894; died November 5, aged 77, of heart block.

Joseph Hamilton Crampton, Seattle; University of Kansas School of Medicine, Kansas City, 1906; past president of the Idaho State Medical Association; served during World War I; died November 9, aged 60.

Edward W. Draper, Gainesboro, Tenn.; University of Tennessee College of Medicine, Memphis, 1935; member of the American Medical Association; died November 17, aged 36, of heart disease.

Frank Eugene Draper, Hyannis, Mass.; Harvard Medical School, Boston, 1886; member of the American Medical Association; a captain in the medical corps of the U. S. Army during World War I; formerly assistant ophthalmic surgeon at the Massachusetts General Hospital and the Boston Dispensary and clinical assistant at the Massachusetts Eye and Ear Infirmary, Boston; died November 23, aged 80, of arteriosclerotic heart disease.

Fred Clifford Eakins, Bannister, Mich.; Western University Faculty of Medicine, London, Ont., Canada, 1899; served during World War I; died in Leamington, Ont., Canada, November 10, aged 68, of carcinoma.

C. Francis Ewing, Wheaton, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1901; member of the American Medical Association; died in St. Francis Hospital, Breckenridge, November 28, aged 72, of coronary thrombosis.

Stanley Theodore Fortune, Ogunquit, Maine; Columbia University College of Physicians and Surgeons, New York, 1916; fellow of the American College of Surgeons; served during World War I; interned at the Presbyterian Hospital in New York; formerly resident physician at the Mary McClellan Hospital in Cambridge, N. Y.; died November 11, aged 57, of angina pectoris due to coronary sclerosis.

George B. Frantz, Coal Center, Pa.; Cincinnati College of Medicine and Surgery, 1886; for many years president of the Peoples Bank and Trust Company in California; died in California November 14, aged 82, of carcinoma of the rectum.

George Bryan Frey, Spartanburg, S. C.; Medical College of the State of South Carolina, Charleston, 1930; on the staff, formerly an intern and resident physician at the Spartanburg General Hospital; interned at the Greenville City Hospital, Greenville; formerly on the staff of the South Carolina State Hospital, Columbia; died November 11, aged 49, of coronary occlusion.

Patrick Joseph Griffin * Fertile, Minn.; Northwestern University Medical School, Chicago, 1913; served during World War I; at one time state food bacteriologist in the Chicago health department; served on the staffs of the Veterans Administration Facility at Hines, Ill., and Alexandria, La.; major, medical reserve corps, U. S. Army, not on active duty; died in the Veterans Administration Facility, Fargo, N. D., October 15, aged 64, of coronary arteriosclerosis and coronary occlusion.

Thomas Frederick Guffin, East Point, Ga.; Atlanta College of Physicians and Surgeons, 1912; member of the American Medical Association; on the staffs of the Grady Hospital and the Georgia Baptist Hospital, Atlanta, where he died November 22, aged 69, of uremia.

George L. Henderson * Conway, Ark.; University of Arkansas School of Medicine, Little Rock, 1907; served during World War I; died November 23, aged 73, of hemiplegia.

Herman William Hesse * Savannah, Ga.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; served as president of the board of education, Kiwanis Club, the alumni associations of the University of Pennsylvania and the Newberry College and as chairman of the health committee of the city council; died November 24, aged 68, of cerebral hemorrhage and myocarditis.

Reuben Chandler Hill * Exeter, Calif.; Medical Department of the University of California, San Francisco, 1901; died November 20, aged 69, of coronary occlusion.

Maximilian Horn, Scarsdale, N. Y.; Medizinische Fakultät der Universität Wien, Austria, 1903; served as dermatologist on the staff of the Vanderbilt Clinic at the Columbia-Presbyterian Medical Center, New York; died in the White Plains Hospital, White Plains, November 25, aged 65, of acute pancreatitis.

Thomas Franklin James, Chicago; Chicago College of Medicine and Surgery, 1916; died in the Mother Cabrini Hospital November 21, aged 67, of cardiac dilatation and lobar pneumonia.

John Franklin Jones, Linn, Mo.; Beaumont Hospital Medical College, St. Louis, 1889; member of the American Medical Association; died November 22, aged 81, of cerebral hemorrhage.

Avedis Herold Kaye, New York; University of Michigan Medical School, Ann Arbor, 1916; on the staff of St. Luke's Hospital; died November 15, aged 58, of cerebral hemorrhage.

William James Knight, Newport News, Va.; Medical College of Virginia, Richmond, 1897; member of the American Medical Association; on the staff of the Riverside Hospital; died November 15, aged 72, of coronary thrombosis.

Edgar Lucius Langrum, Los Angeles; Meharry Medical College, Nashville, Tenn., 1924; served an internship at the Kansas City General Hospital, Kansas City, Mo.; died November 24, aged 46, of acute dilatation of the heart (myocarditis).

Frank Ridgeway Leeds, Michigan City, Ind.; the Hahnemann Medical College and Hospital, Chicago, 1899; served two terms as county coroner; formerly on the staff of the Michigan City Sanitarium; died in Jackson, Mich., November 16, aged 71, of pneumonia.

John Rhodes Lewis • Kansas City, Mo.; St. Louis University School of Medicine, 1925; interned at the Missouri Baptist Sanitarium in St. Louis; on the staff of the Research Hospital; died in St. Charles November 23, aged 48, of coronary thrombosis.

George Anderson MacElree, Philadelphia; Jefferson Medical College of Philadelphia, 1894; member of the American Medical Association; died November 21, aged 70, of coronary thrombosis.

Hugh Monroe Magee • Syracuse, N. Y.; Syracuse University College of Medicine, 1908; on the staff of the Crouse-Irving Hospital, where he died November 19, aged 67, of thrombosis.

Charles Reuben McCreery • Tacoma, Wash.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1902; member of the North Pacific Surgical Association; fellow of the American College of Surgeons; attending surgeon, Tacoma General and St. Joseph's hospitals; died suddenly, November 14, aged 70, of coronary thrombosis.

James Kearney Miller, Sonora, Texas; University of Nashville (Tenn.) Medical Department, 1905; served during World War I; died in the Veterans Administration Facility, Legion, November 10, aged 66, of chronic pulmonary tuberculosis and tuberculosis of the larynx.

Lewis Emory Missimore, St. Louis; St. Louis University School of Medicine, 1904; served overseas during World War I; resident physician on the staff of the Christian Hospital; died November 9, aged 67, of heart disease.

Harland Addison Nichols, Miami, Ariz. (licensed in Texas under Act of 1907, in New Mexico in 1901 and Arizona in 1906); died September 5, aged 81.

Frederick Phillip Parker • St. Louis; Marion-Sims College of Medicine, St. Louis, 1893; died November 18, aged 75, of coronary thrombosis.

George M. Pate, Rowland, N. C.; Medical College of the State of South Carolina, Charleston, 1900; formerly bank president; died in Lumberton November 13, aged 67, of pneumonia.

Albert Victor Pettit • San Francisco; Stanford University School of Medicine, San Francisco, 1919; associate clinical professor of obstetrics and gynecology and acting executive of the department at his alma mater; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; member of the Pacific Coast Society of Obstetrics and Gynecology; since 1929 visiting obstetrician and gynecologist at the San Francisco Hospital; died November 19, aged 53, of coronary occlusion.

Frank E. Plummer, Dayton, Ohio; Baltimore Medical College, 1895; died November 15, aged 76, of cerebral hemorrhage.

Ward Hughes Powell • Minden, Neb.; University of Nebraska College of Medicine, Omaha, 1913; mayor of Minden; county medical adviser; died in the Clarkson Memorial Hospital, Omaha, November 13, aged 62, of coronary occlusion.

Percy Hartley Rushton, Providence, R. I.; Jefferson Medical College of Philadelphia, 1908; member of the staffs of the Homeopathic and Miriam hospitals; died November 18, aged 58, of hypertensive heart disease.

Albert Clifton Sellery • Long Beach, Calif.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1904; fellow of the American College of Surgeons; one of the organizers of the old Long Beach Medical Society, now the Harbor Branch of the Los Angeles County Medical Association; served as president of the board of directors of Seaside Memorial Hospital for six years; died November 23, aged 69.

Hermann K. Stockwell, Salem, Ore.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1902; served overseas with the Canadian Army during World War I; one of the founders of the Salem Clinic; on the staffs of the Salem General and Deaconess hospitals; died November 17, aged 64, of carcinoma of the liver.

Rose Winkler, Azusa, Calif.; Dunham Medical College, Chicago, 1898; died October 25, aged 81, of chronic myocarditis and pernicious anemia.

DIED WHILE IN MILITARY SERVICE

Hugh Grant Cramer, Campbell, Calif.; Stanford University School of Medicine, San Francisco, 1943; served an internship at the Santa Clara County Hospital, San Jose, and a residency at the Monterey County Hospital, Salinas; commissioned a first lieutenant in the medical corps, Army of the United States, on July 17, 1942; died near Pasadena Nov. 11, 1944, aged 28, in an aircraft accident.

Paul Drews Garvin, Boulder, Colo.; University of Colorado School of Medicine, Denver, 1926; member of the American Medical Association; served an internship at the St. Anthony's Hospital in Denver; formerly an intern and resident physician at the Children's Hospital, Denver; at one time assistant professor of clinical pathology at his alma mater; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on Dec. 13, 1940; began active duty in the Army of the United States on March 21, 1941; later promoted to captain and major; died in East Boston, Mass., November 24, 1944, aged 40, of coronary arteriosclerosis.

Herbert Robert Gore • Rochester, Minn.; Long Island College of Medicine, Brooklyn, 1933; interned at the Kings County Hospital in Brooklyn; commissioned a first lieutenant in the medical corps, Army of the United States, on Jan. 9, 1943; began active duty on Feb. 7, 1943; later promoted to captain; died in the Central Pacific area July 26, 1944, aged 36, in an airplane crash.

Lewis Cowan Ramsay • Memphis, Tenn.; University of Tennessee College of Medicine, Memphis, 1936; formerly an intern at the Los Angeles County Hospital in Los Angeles and served a residency in medicine at the Baptist Memorial Hospital; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on Sept. 26, 1938; began active duty in the Army of the United States on March 10, 1941; later promoted to captain and major; killed in an airplane accident in Hanford, Calif., Nov. 4, 1944, aged 34.

Seaton Sailer, Cincinnati; Long Island College of Medicine, Brooklyn, 1931; served an internship at the Roosevelt Hospital in New York and a residency in pathology at St. Luke's Hospital in New York; formerly assistant professor of pathology at the University of Cincinnati College of Medicine; at one time taught in the pathology department at the Medical College of the State of South Carolina, Charleston; member of the American Association of Pathologists and Bacteriologists; on the staff of the Cincinnati General Hospital; commissioned a major in the medical corps, Army of the United States, on Feb. 19, 1942; began active duty in June 1942; later promoted to lieutenant colonel; in charge of pathologic work at the Twenty-Fifth General Hospital in France; died in France Nov. 24, 1944, aged 39, of head injuries, shock and internal injuries accidentally incurred when struck by a truck along a highway.

Donald Meyers Ward • Colonel, M. C., U. S. Army, North Little Rock, Ark.; University of Colorado School of Medicine, Denver, 1933; interned at the Mercy Hospital, Denver; appointed a first lieutenant in the medical reserve corps of the U. S. Army on June 15, 1934; entered the medical corps of the U. S. Army in December 1934; later promoted to captain, major, lieutenant colonel and colonel; died in Guadalcanal Nov. 20, 1944, aged 38.

Rowland Daniel Wolfe • Lieutenant Colonel, U. S. Army, retired, Columbus, Ohio; George Washington University School of Medicine, Washington, D. C., 1908; Army Medical School, 1917; served with the American Expeditionary Forces during World War I; fellow of the American College of Surgeons; at one time superintendent of the Norfolk Protestant Hospital, Norfolk, Va.; entered the medical corps of the U. S. Army as a first lieutenant on Aug. 21, 1917; later promoted to captain, major and lieutenant colonel; retired from active duty on Feb. 28, 1939; recalled to active duty on Sept. 11, 1940; assigned to senior instructor in the ROTC Medical Unit at Ohio State University, where he served as assistant professor of military science; when the army special training program was established in June 1943 he was appointed commanding officer of the medical battalion; died in the Fletcher General Hospital, Cambridge, Sept. 28, 1944, aged 58, of thrombosis of the coronary artery.

Correspondence

THE RH BLOOD FACTORS

To the Editor —In the course of the recent rapid developments in the field of the Rh blood factors it has become necessary to invent a special vocabulary to express the new ideas and describe the new facts which have been discovered. This vocabulary has been tested by actual usage and has the approval of other workers to whom it was sent for their opinions. My purpose in this communication is to publicize the vocabulary more widely for the sake of uniformity in the use of nomenclature by all interested in the subject.

A. S. WIENER, M.D., Brooklyn

Anti rhesus serums. Immune serums prepared in rabbits, guinea pigs, goats and other animals by injecting them with the blood of rhesus monkeys. The term applies to serums like the original experimental serums of Landsteiner and Wiener, which agglutinate the bloods of 85 per cent of all white persons.

Anti Rh₀ human serums. Human serums (usually obtained from mothers of erythroblastic infants) which gave reactions paralleling the anti rhesus serums, also known as standard anti Rh serums.

Rh testing. Examination of blood for the Rh factor, using either anti rhesus serum or anti Rh₀ serum alone.

Rh reaction. Result of the Rh test, namely either Rh positive or Rh negative. When the terms Rh negative and Rh positive are used as adjectives they should be hyphenated, e. g. Rh-positive blood, Rh-negative individuals, but "the blood is Rh positive."

Rh sensitization. The act of becoming sensitive to the Rh factor. This may occur in one of two ways, namely, as a result of a transfusion of Rh-positive blood or as the result of pregnancy with an Rh-positive fetus. Natural sensitivity to the Rh factor does not occur, and only 1 in 25 to 50 Rh-negative persons exposed to the Rh antigen by transfusion or pregnancy becomes sensitized.

Rh factors are three in number designated as Rh₀, Rh and Rh' respectively.

Rh agglutinins. The animal anti rhesus agglutinins are all of the same specificity (85 per cent positive on white persons). The anti Rh agglutinins of human serums have three different specificities corresponding to the three Rh factors namely anti Rh₀ (85 per cent positive on white persons), anti Rh' (70 per cent positive) and anti Rh (30 per cent positive).

Rh agglutinogens, Rh antigens. These are five in number Rh₁ (or Rh'), Rh₂ (or Rh''), Rh', Rh and Rh₀.

Rh antiserums. Antiserums reacting with one or more of the Rh factors. Among human beings, in addition to serums containing only one sort of Rh agglutinin there are some with two Rh agglutinins. Five common varieties of human Rh antiserums are anti Rh₀, anti Rh', anti Rh'', anti Rh' (containing two agglutinins anti Rh₀ and anti Rh') and anti Rh₀'.

Rh genes. The series of allelic genes which determine the various sorts of Rh agglutinogens and Rh blood types. The most common (the standard) genes are six in number *rh*, *Rh'*, *Rh*, *Rh₀*, *Rh₁* and *Rh₂*. When discussing only the results of tests with the standard anti Rh₀ serums, dividing persons into two types, Rh positive and Rh negative, only a pair of genes need be considered, *Rh* and *rh*. Obviously, Rh-positive persons may be either homozygous (genotype *RhRh*) or heterozygous (*Rh rh*) while Rh-negative persons are always homozygous (*rh rh*).

Rh blood types. Tests with anti Rh₀, anti Rh' and anti Rh'' yield eight standard types. The names of these types and their approximate frequencies among white persons in New York City are as follows: type Rh₁Rh₂, 13 per cent, Rh₂, 54.5 per cent, Rh₀, 15 per cent, Rh₀', 2.5 per cent, Rh'Rh'', 1 in about 10,000, Rh', 1.2 per cent, Rh, 0.3 per cent, and Rh-, 13.5 per cent. There are striking differences in the distribution among different races, for example, in Negroes type Rh₀ exceeds 40 per cent, in Mongolian races Rh- is virtually absent, and so on.

Rh typing. Classification of individuals within one of the eight Rh types with the aid of anti Rh₀, anti Rh' and anti Rh'' serums. Note the distinction between "Rh typing" and "Rh testing."

Rh genotypes. The six standard genes pair to yield twenty-one different genotypes. These twenty-one genotypes in turn fall into eight phenotypes.

types identical with the eight Rh blood types because only a distinct type of blood can be distinguished with the anti Rh₀ anti Rh and anti Rh' serums.

Rh classes. For convenience in analyzing genetic results the classification of persons according to their reactions only with anti Rh' and anti Rh'' is convenient. This yields four classes, W, U, V and UV analogous to the four common blood groups. Each class includes a pair of Rh types as follows: class W, Rh₀ and Rh-, class U type, Rh₁ and Rh', class V, types Rh' and Rh₂, class UV, types Rh Rh' and Rh Rh₂.

Hr factor. The factor present in the agglutinogens determined by genes *rh*, *Rh'*, *Rh* and *Rh₀*. Hence only persons belonging to type Rh₁ (provided they belong to genotype Rh₁Rh₁ or Rh₁Rh') or type Rh (rare genotype Rh'Rh) can possibly be Hr negative. Persons belonging to any of the other six Rh blood types are uniformly Hr positive. The common idea that infants with hemolytic disease due to the Hr factor are always Rh negative is wrong, such infants must in fact always be Rh positive.

Anti Hr serum. Serum capable of reacting with blood containing the Hr factor.

Hr tests. Tests with anti Hr serum.

Hr reaction. Results of the Hr tests, namely either Hr positive or Hr negative.

Rh incompatibility. Incompatibility based on difference with respect to one or more of the Rh factors.

Hr incompatibility. Incompatibility with respect to the Hr factor.

Rh blocking serum (antibody). A serum capable of reacting with blood containing the Rh factor but without producing agglutination; thus blocking the action of subsequently added anti Rh serums. A Rh-positive blood treated with Rh blocking serum can no longer be agglutinated by anti Rh serum. To date blocking antibodies of only one specificity have been found, namely, anti Rh.

FOUR GENERATIONS OF SACROILIAC ARTHRITIS

To the Editor —In reference to the editorial comment on four generations of sacroiliac arthritis (THE JOURNAL, Aug 12 1944 p 1044), I am sorry I am stationed outside the continental limits and do not have access to the original article, but the comment must have caused most orthopedic surgeons either to laugh or to have apoplexy.

Is pain in the region of the sacroiliac joint diagnostic of sacroiliac arthritis? Does the presence of sciatica and tingling and swelling of the extremities make it more so?

Were any x-ray studies made in this group of remarkable people, who were for the most part manual laborers and obese? Is not anatomic structure of the lumbar spine also hereditary?

Why do people with obvious arthritis have so few sacroiliac symptoms? Does not the sacroiliac joint fuse early and spontaneously in most cases of true arthritis?

Why go on? If the original article answered these questions you didn't give it justice in your comment. If it did not it does not merit other than condemnation in a supposedly scientific publication.

An analogous set of questions could be asked about the article in the issue of Jan 29, 1944, page 269.

The idea that the sacroiliac joint is responsible for most pains in the back is one of the most persistent in medicine, and its perpetuation is given frequent stimulus even by some orthopedic surgeons.

It is impossible for me to understand why every one looks first at a joint having approximately the surface area of the palm of the hand and having little if any mobility, when there is a much more mobile and mechanically overloaded joint immediately above it which has the approximate area of the thumb nail.

DUNCAN C. McKEEVER, Commander (MC), U.S.N.R.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Misrepresentation by Physicians Employed by Defendant Concerning Extent of Injuries as Tolling Statute of Limitations.—While a passenger in one of the defendant's street cars in 1930 the plaintiff was injured by glass splinters piercing his right eyeball, allegedly because of the negligence of agents of the defendant. Acting in accordance with the directions of the defendant, the plaintiff went to "certain eye specialists" employed by the defendant and submitted to treatment by them at the defendant's expense. The physicians removed the splinters of glass from the eyeball and told him that the eye wounds would heal quickly and that he would "have no further trouble." They instructed him to go to no other physician but to return to them in two years for a final check-up. The plaintiff followed those directions, and when he returned two years later he was advised by them that, aside from the need for glasses, his injured eye was cured and in "perfect condition." In October 1942 the plaintiff perceived for the first time that the vision of his right eye was blurred, and when he consulted another physician in February 1943 it was discovered "that, due to the severance of the cellular system and delicate tissues of the eyeball which occurred at the time of the accident in 1930, and as a proximate result of the injury thereby received, a cataract had completely enveloped the eye and he was totally and permanently blind in the right eye." Notwithstanding the fact that the California statute provides a one year period of limitation for the commencement of an action for an injury resulting from the wrongful act or neglect of another, the plaintiff instituted action against the defendant in June 1943, alleging a causal relation between the negligence of the agents of the defendant in 1930 and in his loss of sight that followed in 1943. He contended that the applicable one year statute of limitation did not apply because the physicians employed by the defendant fraudulently concealed from him the nature of his injuries and that therefore the statute should not begin to run until he had ascertained his injuries. The trial court sustained a demurrer interposed by the defendant based, in effect, on the assumption that the statute of limitations precluded the maintenance of an action by the plaintiff, and the plaintiff eventually appealed to the Supreme Court of California.

In resolving the question of the correctness of the trial court's order, said the Supreme Court, the legislative policy in prescribing a period of limitation for the commencement of actions must be borne in mind. "The statute of limitations is a statute of repose, enacted as a matter of public policy to fix a limit within which an action must be brought, or the obligation is presumed to have been paid, and is intended to run against those who are neglectful of their rights, and who fail to use reasonable and proper diligence in the enforcement thereof. . . . These statutes are declared to be 'among the most beneficial to be found in our books.' 'They rest upon sound policy, and tend to the peace and welfare of society'; . . . The underlying purpose of statutes of limitation is to prevent the unexpected enforcement of stale claims concerning which persons interested have been thrown off their guard by want of prosecution." 1 Wood, Limitations, pp. 8, 9. However, it is provided by statute in this state that when the liability accrues by reason of fraud, the statute will not run until the fraud is discovered. Code Civ. Proc. sec. 338, subd. 4. Similarly, the courts of this state have held that when the defendant is guilty of fraudulent concealment of the cause of action the statute is deemed not to become operative until the aggrieved party discovers the existence of the cause of action. See Dawson, Undiscovered Fraud and Statutes of Limitation, 31 Mich. L. Rev. 591, at p. 593, notes, and Fraudulent Concealment and Statutes of Limitation, id. 875 at 877. In *Kane v. Cook*, 8 Cal. 449, for instance, it was held "that in all cases a fraudulent conceal-

ment of the fact, upon the existence of which the cause of action accrues, is a good answer to the plea of the Statute of Limitations."

The defendant contended that when a personal injury results from the wrongful act or neglect of another the cause of action accrues when the breach of duty occurred, and the statute then commences to run, on the theory that since the breach of duty of care and consequent impact followed by injury cannot be concealed, the fraud alleged to have been committed by the defendant cannot result in concealment of the cause of action, and therefore there is no fraudulent concealment within the meaning of the decisions previously referred to. But, answered the court, the plaintiff's right to relief in such cases is not dependent on technical legal definitions. In reality the ground of relief is that the defendant, having by fraud or deceit concealed material facts and by misrepresentations hindered the plaintiff from bringing an action within the statutory period, is estopped from taking advantage of his own wrong. The statute of limitations was intended as a shield for protection against stale claims, but a defendant may not use it to perpetrate a fraud on otherwise diligent suitors. Technical rules as to when a cause of action accrues apply therefore only in those cases which are free from fraud committed by the defendant. Section 338, subdivision 4, Code of Civil Procedure, recognizes the nonapplicability of those technical rules where the fraud of the defendant may be so concealed that, in the absence of circumstances imposing greater diligence on the plaintiff, the cause of action is deemed not to accrue until the fraud is discovered. Otherwise, in such cases, the defendant, by concealing his fraud, would effectively block recovery by the plaintiff because of the intervention of the statute of limitations. The same conclusion governs when the defendant under duty of disclosure has concealed known essential facts on which to base a recovery against him and thereby has hindered the plaintiff from bringing his action until after the statute would otherwise have terminated the period of limitation. We are not here called on to determine what acts of concealment might under the circumstances be deemed a legitimate hindrance to litigation. Whether in itself it is an actionable fraud or merely suffices to toll the statute on the original obligation, the breach of a duty to disclose known facts with the intention to and which does hinder commencement of an action until the action would be outlawed is a fraud practiced on the plaintiff which in conscience estops the defendant's reliance on the statute of limitations. The cases relied on by the defendant wherein it has been stated that the cause of action accrues at the time of the injury, and that the late discovery of the person responsible therefor or of the extent of the injury does not postpone the commencement of the statutory period, have heretofore been distinguished by this court as cases where fraud and deceit were not involved.

The defendant relied on two cases in particular as support for its position that fraudulent concealment of the extent of the injury cannot amount to fraudulent concealment of facts giving rise to the cause of action. In one, *Maloney v. Brackett*, 275 Mass. 479, 176 N. E. 604, the plaintiff sued two physicians for malpractice, alleging fraudulent concealment as excuse for late filing, and the trial court entered judgment on directed verdicts for the defendants. In overruling the plaintiff's exceptions, it was held that the failure of a doctor to disclose a cause of action to a patient could not be found to be a breach of his professional duty without evidence that he knew or believed that a cause of action existed; that there was no evidence that either the defendant knew or believed that he had performed or assisted in the performance of an unnecessary operation, and that the prediction as to the plaintiff's recovery made before the operation had no tendency to prove that they did not in good faith consider the operation advisable. In the other, *Ogg v. Robb*, 181 Iowa 145, 162 N. W. 217, L. R. A. 1918C, 981, the plaintiff was burned by x-ray treatments administered by the defendant in 1901. The burnt area did not heal but became malignant. In 1915 the plaintiff sued, alleging malpractice and fraudulent concealment by misrepresentations of the temporary character of the burn. A demurrer to the complaint was su--

tained. In holding that the statute of limitations was not suspended, the court attributed the representation of the defendant regarding the nature of the burn as an expression of opinion only. The statement of the facts considered in those cases, said the court, makes them readily distinguishable from the proposition contended for by the plaintiffs. To the contrary of defendant's contention the following malpractice cases held that fraudulent concealment would foreclose the defense of the statute of limitations: *Groendal v. Westrate*, 171 Mich. 92, 137 N. W. 87, Ann Cas. 1914B, 906; *Schmucking v. Mayo*, 183 Minn. 37, 235 N. W. 633. In the *Schmucking* case it was said that in the presence of a fiduciary and confidential relation the fraud may more readily be perpetrated, designating that of physician and patient as such relationship, citing *Groendal v. Westrate*, supra, and that it was well to bear in mind that the statute does not run against actions for fraud until the fraud is discovered. It was also said:

"... a person should not be permitted to shield himself behind the statute of limitations where his own fraud has placed him. He should not be permitted to profit by his own wrong, and it would strike the moral sense strangely to permit him to do so. We are not aware of any principle of law or equity which affords immunity to a fraudulent defendant who by his deceitful practice induces a creditor to forbear his efforts to collect his debt until after it has become barred by the lapse of time."

The confidence, continued the court, growing out of the relationship of physician and patient imposes on a physician the duty of refraining from fraudulent concealment, that is, the duty of disclosure when he has knowledge of the facts. If that is the result in malpractice cases, then all the more was the defendant herein under a duty of disclosure when it voluntarily undertook to treat the plaintiff's injuries caused by its own breach of duty. Where there is a duty to disclose, the disclosure must be full and complete, and any material concealment or misrepresentation will amount to fraud sufficient to entitle the partly injured thereby to an action. *Kimball v. Pacific Gas & Elec. Co.*, 220 Cal. 203, 30 P. (2d) 39; *Vance v. Supreme Lodge*, 15 Cal. App. 178, 114 P. 83. Since its voluntary undertaking placed on the defendant the duty to disclose to the plaintiff the full extent of his injuries and the probable future disability to be expected therefrom, its false representation designed to conceal facts known to it and intended to prevent plaintiff's consulting other physicians, and thus hinder him from bringing action until after the running of the statutory period of limitations, must be deemed to amount to fraud on the plaintiff and to excuse any greater diligence on his part under the facts disclosed by the complaint. No fact as to the plaintiff's condition is alleged which could be deemed to have put him on earlier notice.

The only remaining question, said the court, is whether the defendant was bound by the alleged deceit and misrepresentations of its agents, the physicians it employed to care for the plaintiff. The agents' alleged deceit was not intended for their own benefit but for the pecuniary advantage of the defendant, their principal. If its agents' deceit should succeed, the defendant would reap the pecuniary gain therefrom. Thus its agents have employed the alleged deceit for the sole benefit of the defendant, and in such a case the facts must be deemed to be within the defendant's knowledge. The same principles therefore apply to make it unconscionable for the defendant to rely on the bar of the statute. As was said in *Lightner Mining Co. v. Lane*, 161 Cal. 689, 120 P. 771, Ann. Cas. 1913C, 1093, the fraud of the agents will be imputed to the principal for the purpose of preventing the running of the statute of limitations whether the principal was aware of it or not. The injustice of allowing such fraud to become successful by reason of lapse of time and concealment is an injustice to the plaintiff, and it is precisely the same in effect and extent whether the fraud is that of the defendant or its agents. The defendant, having received the benefit of its agents' fraud, has no equity in its favor.

The court accordingly concluded that the plaintiff had timely instituted the action against the defendant after his discovery of the fraud alleged and that the trial court erred in sustaining the defendant's demurrer. The judgment in favor of the defendant company was accordingly reversed.—*Pashley v. Pacific Electric Co.*, 153 P. (2d) 325 (Calif., 1944).

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, January 27, page 244.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, June 26-28. Sec., Dr. B. F. Austin, 519 Dexter Ave., Montgomery 4.
ALASKA: Juneau, March. Sec., Dr. W. M. Whitehead, Box 561, Juneau.
ARKANSAS: * *Eclectic*. Little Rock, June 7. Sec., Dr. C. H. Young, 1415 Main St., Little Rock. *Medical*. Little Rock, June 7-8. Sec., Dr. D. L. Owens, 701 Main St., Little Rock.
CALIFORNIA: *Oral*. Los Angeles, March 3. *Written*. Los Angeles, Feb. 27-March 2. Sec., Dr. Frederick N. Scatenia, 1020 N. St., Sacramento 14.
COLORADO: * Denver, April 3-6. Final date for filing application is March 19. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.
CONNECTICUT: * *Homeopathic*. Derby, March 12-13. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven. *Medical*. Examination, March 13-14. *Endorsement*. March 27. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven.

DELAWARE: Examination, Dover, July 10-12. *Reciprocity*. Dover, July 17. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.
DISTRICT OF COLUMBIA: * *Reciprocity*. Washington, March 12. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.
FLORIDA: * Jacksonville, June 25-26. Sec., Dr. Harold D. Van Schaick, 2736 S. W. Seventh Ave., Miami 36.
ILLINOIS: Chicago, April 3-5. Superintendent of Registration, Department of Registration and Education, Mr. Philip Harman, Springfield.

KANSAS: Topeka, Feb. 19-20. Sec., Board of Medical Registration and Examination, 905 N. Seventh St., Kansas City 10.
KENTUCKY: Louisville, June 18-20. Sec., State Board of Health, Dr. Philip E. Blackerby, 620 S. Third St., Louisville 2.

MAINE: Portland, March 13-14. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

MARYLAND: Baltimore, June 19-22. Sec., Dr. J. T. O'Mara, 1215 Cathedral St., Baltimore.

MASSACHUSETTS: Boston, March 13-16. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413-F State House, Boston.

MISSISSIPPI: Jackson, Feb. 9. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson 113.

MONTANA: Helena, April 2-4. Sec., Dr. O. G. Klein, First Nat'l. Bank Bldg., Helena.

NEVADA: *Endorsement*. Carson City, Feb. 5. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: Concord, March 8-9. Sec., Board of Registration in Medicine, Dr. D. G. Smith, 77 Main St., Nashua.

NEW JERSEY: Trenton, June 19-20. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: * Santa Fe, April 9-10. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

NORTH CAROLINA: *Reciprocity*. Raleigh, Feb. 5. Sec., Dr. W. D. James, Hamlet.

NORTH DAKOTA: Grand Forks, July 3. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OHIO: *Endorsement*. Columbus, April. Columbus, June. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: * Oklahoma City, June 14-16. Sec., Dr. J. D. Osborn, Jr., Frederick.

PENNSYLVANIA: April 10-13. Act. Sec., Bureau of Professional Licensing, Department of Public Instruction, Mrs. M. G. Steiner, 358 Education Bldg., Harrisburg.

RHODE ISLAND: * Providence, April 5-6. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, June 25-27. Sec., Dr. N. B. Heyward, 1329 Blandina St., Columbia.

VERMONT: Burlington, June. Sec., Dr. F. J. Lawless, Richmond.

VIRGINIA: * Richmond, June 20-23. Sec., Dr. J. W. Preston, 30½ Franklin Rd., Roanoke.

WEST VIRGINIA: Charleston, Feb. 26-28. Commissioner, Public Health Council, Dr. J. H. Offner, State Capitol, Charleston 5.

WISCONSIN: * Milwaukee, June 26-28. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

WYOMING: Cheyenne, Feb. 5-6. Sec., Dr. M. C. Keith, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

CONNECTICUT: Feb. 10. Address State Board of Healing Arts, 250 Church St., New Haven 10.

DISTRICT OF COLUMBIA: Washington, April 23-24. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

FLORIDA: DeLand, June 1. Sec., Dr. J. F. Conn, John B. Stetson University, DeLand.

IOWA: Des Moines, April 10. Dir., Division of Licensure and Registration, Mr. H. W. Greffe, Capitol Bldg., Des Moines.

MICHIGAN: Ann Arbor and Detroit, May 11-12. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

MINNESOTA: Minneapolis, April 3-4. Sec., Dr. J. C. McKinley, 126 Millard Hall, University of Minnesota, Minneapolis 14.

NEBRASKA: Omaha, May 1-2. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln.

NEW MEXICO: Santa Fe, Feb. 12. Sec., Miss Marion M. Rhea, State Capitol, Santa Fe.

OKLAHOMA: Oklahoma City, April 9. Sec., Dr. J. D. Osborn, Jr., Frederick.

OREGON: Portland, March 3. Sec., Board of Higher Education, Mr. C. D. Byrne, University of Oregon, Eugene.

RHODE ISLAND: Providence, Feb. 14. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Yankton, June 19. Sec., Dr. G. M. Evans, Yankton.

TENNESSEE: Memphis, March 27-28. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- Effect of Temperature, Humidity and Glycol Vapor on Viability of Air Borne Bacteria. K B DeOme and Personnel of U S Navy Medical Research Unit No 1—p 239.
- Investigations on Mosquito Transmission of Plasmodium Lophurae Cogge shall 1938. G M Jeffery—p 251.
- Avian Salmonellosis: Types of Salmonella Isolated and Their Relation to Public Health. W R Hinshaw, E McNeil and T J Taylor—p 264.
- *Seasonal Patterns of Measles and Chickenpox. Mildred Weeks Wells—p 279.
- Dynamics of Meningococcal Infections and Effect of Chemotherapy. J J Phair and E B Shoenbach—p 318.

Seasonal Patterns of Measles and Chickenpox.—Weeks Wells asserts that the rate of spread of an air borne infection is proportionate not only to the concentration of persons susceptible to it but also to the concentration of the causative micro-organisms in the varied atmospheres which they breathe. Rate of spread refers to the number of cases arising on the average from each previous case per unit of time corresponding to the incubation period. The concentration of micro-organisms in an enclosed inhabited atmosphere is an equilibrium between rate of addition (proportionate to the number of infective persons) and their specific infectivity—stage of disease, coincidence of a cold and so on—and rate of elimination, determined by ventilation. Epidemiologists have long been interested in the relation which the concentration of the susceptible in a population bears to the rate of spread of an epidemic disease, and it is now recognized that the "cyclical or intrinsic periodicities" is a function of the concentration of the susceptible. If a disease is air borne, certain consequences as to its seasonal patterns necessarily follow: 1. Since the rate of spread of the disease is proportionate to the concentration of the causative micro-organisms in inhabited atmospheres and since this concentration depends on ventilation, it follows that (a) in those localities where there is considerable difference between summer and winter temperatures, incidence of the infection will likewise show a pronounced sensitivity to seasonal change—that is, the ratio between maximum and minimum numbers of cases for given fractions of the year will be high; (b) seasonal patterns will vary with climate, since this affects the length of the season when ventilation is impeded by closed windows. 2. Since the rate of spread is proportionate to concentration of the susceptible, (a) seasonal patterns will vary in years of high and low incidence and (b) seasonal patterns will vary in urban and rural communities. The seasonal patterns of spread of measles and chickenpox, while differing greatly from each other, are both entirely compatible with the theory of transmission by air borne droplet nuclei. This does not prove the validity of the theory. Such proof can come only with the accumulation of evidence from many fields or from the successful control of respiratory diseases by air purification. The seasonal patterns of scarlet fever, on the other hand, suggest that means of transmission less amenable to control by ventilation than are droplet nuclei assume an important role in its spread.

- Effects of Sulfanilamide Locally Implanted in Clean Wounds. J. I. Southworth—p 245.
- Improved Technique for Preparing Buried Dermal Graft in Hernial Repair. J. V. Scola—p 249.

Relationship Between Hydrocele and Hernia.—O'Crowley and Herzlich classify hydroceles into those of the testis, those of the cord and complications of these forms. They found 7 hernias in a series of 20 cases treated surgically. The literature gives the impression that this association is infrequent. Of the 20 cases of surgically treated hydrocele 3 involved congenital hydroceles all associated with hernia and 1 of these with an undescended testis; the rest were of the ordinary type. In all cases of hernia either intestinal or omental tissue was present in the sac; it was in the congenital hydrocele sac or in a separate pouch alongside the cord. All hernias were of the indirect variety. Of the 20 cases, only 1 hernial hydrocele and 3 uncomplicated hydroceles were on the left side. Most were diagnosed at operation, because frequently the hernia could not be discovered with certainty until then. Those communicating directly with the peritoneal cavity could not be diagnosed on examination unless the hernia was fairly large. The authors stress the frequency of association of hydrocele and hernia in the ages between 19 and 30. They recommend the inguinal approach for the repair of hydrocele in view of the possibility of an associated hernia.

- Primary Malignant Tumors of Small Bowel. R. F. Warren—p 451.
- Tuberculous Lesions of Other Organs Concurrent with Renal Tuberculosis. K. F. Davis—p 457.

Estrogenic Origin of Uterine Fibromyomas.—Shute analyzed the histories of 130 consecutive unselected women with fibromyomas for evidence of old functional menorrhagias or hypothyroid states. Fifty-two per cent of these gave a history of menorrhagia, probably functional, in the second decade. Sixty-three per cent of them were hypothyroid. The author was impressed by the sequence of functional menorrhagia in the

early decades, ending in organic menorrhagia in later decades. Furthermore, menorrhagia that seemed to be due to fibroid tumors in many instances quickly responded to treatment with antiestrogen such as thyroïd or testosterone propionate. It is hoped that the gynecologist of the future will not be satisfied with the mere diagnosis and extirpation of fibromyomas. He will hope to recognize them early and prevent their growth and interference with function, or, better still, he will hope to recognize in the first two decades of life those women who are apt to develop fibroids later and take preventive measures accordingly.

Toxicity of DDT.—According to Woodard, DDT is quite insoluble in water but soluble in oils and organic solvents. The material used in this investigation was either dissolved in corn oil or used in the dry powdered state. Several species of animals and test methods were used. The authors were especially interested in the differences in susceptibility which were manifested both within and between species. DDT was found to be acutely toxic by mouth to small laboratory animals such as rats, mice, guinea pigs, rabbits and chicks in doses ranging from 150 to 750 mg. per kilogram of body weight. Acute doses may produce anorexia, tremors, depression and death. DDT is capable of causing subacute toxicity when given in small amounts in the diet for periods of from three days to twenty weeks. Definite signs of toxicity are produced by levels in the diet of 0.05 per cent (500 parts per million) for rats and mice, 0.1 per cent for guinea pigs and less than 0.05 per cent for growing chicks. Characteristic of DDT poisoning is the wide variation in individual susceptibility, making the estimate of a safely tolerated dose extremely difficult.

Penicillin in Sulfonamide Resistant Gonorrhea.—Scarcello reviews 200 cases of sulfonamide resistant gonorrhea in which treatment with penicillin was used. The penicillin was dissolved in sterile distilled water, 100,000 units being dissolved in 20 cc. The patients are given five intramuscular injections of 4 cc. (20,000 units) at two or three hour intervals until a total of 100,000 units has been administered. There were 27 patients who required two or more courses of penicillin. Twenty-nine patients developed complications. There were 3 patients with gonorrheal arthritis all of whom had an immediate good response to penicillin. Four patients with prostatic abscess showed immediate response to penicillin therapy. Seventeen patients had an acute epididymitis on entry, and 5 developed epididymitis following penicillin. Penicillin had little or no effect on this condition. Sulfonamide therapy should be continued as long as possible to keep the infection localized, even though clinical improvement is not noted. Irrigations and instillations, the cause of the majority of complications, should be avoided. The observations on the 200 cases convinced the author that penicillin has proved its worth in sulfonamide resistant cases of gonorrhea. All patients were returned to duty in one third of the time previously required.

Nutrition Survey in Rural North Carolina.—Milam and Anderson carried out a nutrition survey in Wayne County, in eastern North Carolina, where hookworm and malarial infections are only moderately prevalent. The first survey, an intensive one, was limited to one rural township of 5,000 population, of which 10 per cent, predominantly school children, were examined. The second, or "extensive, survey" comprised 900 individuals and was made up of 200 families. These families (120 white, 80 Negro) were distributed among the owner, tenant

and sharecropper population in proportion to the size of their groups. Vitamin C dietary intake data show for white and Negro groups that 40 per cent and 50 per cent respectively consumed less than one fourth of the recommended allowance. However, studies on the plasma revealed that the zero plasma levels are not so frequent as the low dietary intakes would presuppose. No scurvy was diagnosed. Vitamin A figures were much more favorable. Only 5 and 8 per cent respectively of white and Negro groups ingested under 25 per cent of the recommended allowances. More than 40 per cent of all groups except white children ingested the full recommended amount of 5,000 international units daily. Over 50 per cent of all groups consumed less than half of the recommended allowances of both thiamine and riboflavin. Calcium and iron intakes were considerably less favorable in Negro than in white groups. Forty-three per cent of white persons and 25 per cent of Negroes ingested three fourths of the recommended level of calcium. The protein intake data show that 60 per cent of white adults and 50 per cent of Negro adults ingested three fourths or more of the recommended level of 70 Gm. daily while 8.3 per cent of white adults and 12.6 per cent of Negro adults ingested less than half. The mean intake of calories remained constantly under 2,000. Home made biscuits characteristically baked from white flour with baking powder or soda added were the chief source of calories, constituting approximately 20 per cent of the calories for all groups. Fat pork was the second caloric source for adults and corn bread the third. The foods in order of their contribution to calories were, for white children, biscuit, milk, white bread, fat pork, cocoa and ice cream, and corn bread; for colored children, biscuit, corn bread, fat pork, fish, lean pork and milk. The authors evaluate vascularization of the cornea, gingivitis, hyperkeratotic skin and height-weight records. They conclude that, in view of the fact that the dietary intake levels were far below the standards recommended by the National Research Council, better planned dietaries with greater intake of protective foods seem to be the need. A nutritional educational campaign or improvement in economic, social and cultural conditions may be the essential basic procedure.

The Enigma of Pellagra.—According to Remington public health statistics show a decline in pellagra mortality rates in thirteen Southern states between 1928 and 1940 of 77 per cent, this being a much higher rate of change than for any other endemic disease. In South Carolina, where the death rate was highest, this decline has continued through 1943, amounting to 91 per cent of the rate in 1928. In this state there has also been a parallel drop in incidence of the disease, indicating that the improvement is due to some combination of causes which affects the entire population and not to remedial measures. The annual distribution of bulk dried brewers' yeast parallels incidence, indicating that it was used for treatment rather than for prevention. Distribution of money or food by federal relief agencies during the years 1935-1938 had no favorable effect on pellagra, there having been a slight increase in both incidence and mortality during those years. Mortality among Negroes is higher than among white persons but has decreased more rapidly. The means by which this population fraction of lowest economic status has been able to make superior progress in eradicating pellagra is not clear. The fact remains that the Negroes of the South, with less to do with and with less attention from welfare workers, have been able to make substantially greater progress in reduction of pellagra than has the white population. The fact that they were able in depression years to show a decrease of 77 per cent as compared with 40 per cent for white persons (in South Carolina) is evidence that since 1928 the pellagra death rate has been influenced by other factors sufficiently potent to overcome in part the economic one. The female death rate from pellagra is about 2.5 times the male in Negroes and 1.75 in white persons. This sex difference is limited to the years of active sex life and suggests further investigation into the etiology of pellagra. Since pellagra incidence and mortality rates have fallen, it can be inferred that general malnutrition may have decreased to a somewhat similar degree. It is predicted that these rates will continue to decline and that the rate of decline may be accelerated by such efforts as the national nutrition program and the enrichment of refined cereal products with vitamins.

Plasma Acid Phosphatase in Carcinoma of Prostate.—Watkinson and his collaborators describe a method for estimating acid phosphatase and values obtained for plasma acid and alkaline phosphatase in various clinical conditions and in normal controls, and for acid phosphatase in seminal fluid. Two specimens of seminal fluid from a case of eunuchoidism contained relatively negligible amounts of acid phosphatase. Of 10 cases of prostatic carcinoma, 6 showed a raised acid phosphatase content in the plasma; in 5 of these there was x-ray evidence of metastases in bone. Several of the results do not show great distinction between prostatic carcinoma with metastases and Paget's disease. The behavior of the plasma phosphatases in cases of carcinoma of the prostate in which the plasma acid phosphatase was originally raised was followed during treatment with diethylstilbestrol. The response shows a uniformity of pattern, the acid phosphatase falling abruptly to a normal level, which is then maintained for considerable periods, with a rise in alkaline phosphatase followed by a gradual fall. In 10 cases of carcinoma of the prostate 4 showed some degree of regression of the primary tumor under treatment with diethylstilbestrol, and secondary deposits in lymph nodes underwent regression in 3 cases. X-ray examination at three monthly intervals in cases with metastasis to bone revealed in some a progressive increase in density, while in others the deposits became more numerous during treatment or increased in size. With one exception all cases showed some symptomatic and general improvement in relief from pain, lessening of frequency of micturition, gradual increase in hemoglobin level, improvement in appetite and gain in weight.

Tragedy of Malignant Melanoma.—Tod thinks that there is no greater tragedy in medicine than the death from multiple metastases of a young patient who had been in perfect health until a small pigmented mole was removed for cosmetic reasons. Unfortunately ignorance regarding the great danger of interfering with any pigmented mole or "birthmark" still prevails. Casual excision, ligation or cauterization of pigmented moles has led to the rapid death of 34 patients referred to the Holt Radium Institute when the appearance of recurrence or metastasis gave the alarm. These 34 patients were among 100 seen

at the institute. It is never justifiable to remove, for cosmetic reasons, a pigmented lesion which shows no sign of active growth. A patient who wishes to have such a lesion removed must be strongly advised to leave it alone and warned that any form of minor treatment is dangerous. If he insists on removal, the operation must be in every way as radical as if the lesion showed signs of active growth. A patient may come for advice because a pigmented lesion has begun to grow (a) spontaneously, (b) after injury or (c) after injudicious treatment. If there is no doubt that a lesion likely to be a melanoma is growing, treatment must be radical. A patient may come with a pigmented lesion, which may or may not show signs of growth, and enlarged regional lymph nodes. If the regional lymph nodes are involved the treatment is surgical. Lymph nodes should not be treated by irradiation except for palliation when they are completely inoperable. A patient, when first seen, may have multiple metastases. When metastases are already present beyond the regional lymph nodes, cure is practically impossible. Palliative irradiation may be tried and sometimes prolongs life and prevents suffering by delaying the local breakdown of lesions on the surface until metastases in lung or liver end life in a more merciful way. The author lists results obtained among the aforementioned 100 patients: 50 are dead, and of the 50 who are alive 40 are well, whereas 10 have recurrences.

Refrigeration Anesthesia for Amputations of Extremities.—Animal experiments carried out at the Sklifassovskiy Institute (Moscow) demonstrated that lowering the temperature of tissues between 5 and 10 degrees centigrade obtains satisfactory anesthesia for operative intervention. Refrigeration below this point leads to irreversible alterations in the tissues, while temperatures above 10 degrees do not procure adequate anesthesia of the tissues. Circulating blood in the vessels becomes concentrated under the influence of refrigeration, but its morphologic elements remain unaltered. Lowering of the temperature of the tissues causes lowering of biologic qualities of living protoplasm and interrupts nervous impulses, conductivity and sensitivity of nerve endings. Gradual cooling induces anesthesia without painful sensations. The pain sense is the first to disappear, followed by loss of the thermal sense and finally by loss of the tactile sense. Microscopic studies of the tissues refrigerated to 5 C. revealed no structural changes from normal tissues. Apparently the changes in an anesthetized extremity are of molecular alteration of colloid substances and cannot be recognized by microscopy. The advantages of this method of anesthesia, as observed in amputations of lower extremities in 100 cases of street trauma, demonstrated the safety of the method, complete anesthesia, elimination of narcotics, absence of operative shock and postoperative complications, and arrest of infection, including that of gas gangrene. The stumps healed readily. There were only 4 instances of postoperative suppuration of the wound. The growth of the micro-organisms is arrested during the process of refrigeration. After the period of refrigeration the micro-organisms again display capacity for growth and multiplication. However, their number is considerably diminished. The effect of refrigeration on shock is explained particularly by the alleviation of pain, while application of a tourniquet and refrigeration interferes with formation of toxins and their absorption. Refrigeration anesthesia is particularly indicated for sick, emaciated and septic patients.

Book Notices

Radiation and Climatic Therapy of Chronic Pulmonary Diseases with Special Reference to Natural and Artificial Heliotherapy, X-Ray Therapy, and Climatic Therapy of Chronic Pulmonary Diseases and All Forms of Tuberculosis. Edited by Edgar Mayer, M.D., F.A.C.P., F.A.C.C.P., Assistant Professor of Clinical Medicine, Cornell University Medical College, New York. Cloth. Price, \$5. Pp. 393, with illustrations. Baltimore: Williams & Wilkins Company, 1944.

This volume is intended for both the chest specialist and the general practitioner. It deals with light, x-ray and climatologic therapy as applied to chronic pulmonary diseases, including all forms of tuberculosis. The twenty-six chapters are prepared by twenty-three different authors. The section on light therapy consists of chapters on the physics of light radiation, physiologic action of light and sources of light. The section on artificial light therapy includes discussions of the effects of light from artificial sources on tuberculosis of the lungs, pleura, pharynx, trachea, bronchi, intestine, peritoneum, lymph nodes, urogenital organs, skin, middle ear and eye. The section on solar radiation and climatotherapy includes chapters on climate and weather effects on respiratory infections, solar radiation and climatotherapy in a cool, low altitude in the high, sunny Colorado Rockies, in the sunny Southwestern Desert, in a cold, moderate altitude, and solar radiation of tuberculosis in high, sunny altitudes. The section on x-ray therapy includes discussions of chronic nontuberculous mediastinal and pulmonary disease, intrathoracic tumors and tuberculosis of the cervical lymph nodes, of the intestine and peritoneum, skin, pelvic organs, bones and joints. Two chapters are devoted to the surgical versus conservative therapy in the treatment of tuberculosis of the bones and joints. An excellent summary is presented by Dr. Mayer on climatic, x-ray and light therapy of chronic pulmonary diseases and all forms of tuberculosis. This is a timely book and one much needed, since there has been considerable confusion in the minds of physicians regarding the efficacy, particularly of light and climate, in the treatment of various diseases. The editor's long experience in this field qualified him to select those persons best prepared to present the various subjects. Therefore in this book is to be found the latest and most authentic information on the subjects presented. It can be highly recommended to physicians everywhere.

Neurology of the Eye, Ear, Nose, and Throat. By E. A. Spiegel, M.D., Professor of Experimental and Applied Neurology and Head of Department of Experimental Neurology, Temple University School of Medicine, Philadelphia, and I. Sommer, M.D., Consultant Ophthalmologist and Otolaryngologist, Chicago Eye and Ear Hospital. Cloth. Price, \$7.50. Pp. 667, with 118 illustrations. New York: Grune & Stratton, 1944.

This is a tremendous piece of work. It seems to the reviewer that a separate book on the neurology of the eye and another on the neurology of the ear, nose and throat should have been written. By doing this more emphasis could have been placed on clinical cases and detail. There are four parts: neurology of the ear, neurology of the eyes, neurology of the nose, mouth, pharynx and larynx, and local symptoms of the brain stem and the cerebrum. This book is an English edition of the authors' oto-ophthalmo-neurologie except that it has been almost completely rewritten. Anatomy, physiology and pathologic disturbances of the nervous mechanisms related to the eye, ear, nose and throat are outlined. There are 1,719 references in the bibliography. The book is recommended to eye, ear, nose and throat residents as well as to neurologists interested in the eye, ear, nose and throat.

Poisonous Plants of Hawaii. By Harry L. Arnold, M.D. Boards. Price, \$2. Pp. 71, with 24 illustrations. Honolulu: Tongg Publishing Company, 1944.

This little book contains concise discussions of the common and dangerous plants of Hawaii, some notes on allergic reactions and Hawaiian mushroom-like fungi, a comprehensive list of all plants which have been listed as being poisonous and a bibliography. The volume has numerous illustrations and gives much useful information about poisonous plants and their remedial measures when needed. The volume should find wide use by the general practitioner in Hawaii.

Diseases of the Nose, Throat and Ear: A Handbook for Students and Practitioners. By I. Simson Hall, M.B., Ch.B., F.R.C.P.E., Surgeon to the Royal Infirmary, Edinburgh. Third edition. Cloth. Price, \$4.50. Pp. 459, with 80 illustrations. Baltimore: William Wood & Company, 1944.

The first edition of this manual was published in 1937. Other editions are that of 1941 and the present one. Like many of its kind, this work is based on lectures to students and general practitioners. Preceding each section there is a brief sketch of the anatomy concerned, but no bibliography is offered, although "the student is expected to refer to larger works." The commoner diseases, deformities and injuries of the nose are satisfactorily described, such as deviated septum, polypi, the various types of "rhinitis" including atrophic and syphilitic, hemorrhage, diphtheria and sinusitis. On page 163 under the heading "Removal of Adenoids Alone" the author describes the procedure of adenoidectomy under ethyl chloride and states that "in certain cases . . . it is desirable to remove the adenoids and to leave the tonsils . . . the converse is never the case." He takes the view that if there has been no history or clinical sign of "tonsil trouble" the tonsils may be left. This is contrary to American thought and practice. Tonsillectomy here is recommended as a preventive of subsequent throat infections, for it is thought to be ultraconservative to attempt to "save the tonsils" since later removal is likely to become obligatory. However, some authorities still cling to the British point of view. The final section of the book deals with the ear and is quite complete as to the types of otitis media seen in general practice and the complications arising therefrom. It is questionable, nevertheless, whether a detailed description of radical mastoidectomy and labyrinthectomy need be included in a handbook of this sort. The author's view on the use of the sulfonamides is safe and sane. He agrees that they are to be administered in the hospital only and under laboratory control.

Lumbo-Sacral Strain: A Handbook on Its Relief and Cure by Manipulative Therapy. By H. Vincent Langley. With foreword by N. Howarth Hignett. Cloth. Price, 6s. Pp. 24, with 12 illustrations. London: Research Books, Ltd.; distributed by Wm. Heinemann, Ltd., 1944.

This small volume begins with a foreword from a layman that is nothing more than a testimonial. In the introduction one finds that the same layman has corrected proofs of the book. In the introduction "the writer has attempted to demonstrate that lumbosacral and rotating lumbosacral strains are produced through faulty mechanism of the pelvis." This is not new to the orthopedic profession in any country. Although the author states that the physical signs are pathognomonic, a good observer would disagree because there are many other conditions of the low back which show the same signs, and here lies the danger of putting the book into the hands of practitioners who, for the most part, are not interested in orthopedic problems. The writer does not go far enough when he ascribes the causes of increased inclination of the pelvis to muscular relaxation. It has been demonstrated that a contracted fascia lata is also a cause. The symptoms described are sketchy and the area of tenderness is not often along the superior gluteal nerve but is due to spasm of the upper part of the gluteal muscle. His reference to high heels is not borne out by the facts; more men than women are now affected by lumbosacral strain. As a matter of fact, raising a heel may relieve a lame back within a few days. It is difficult to believe that the springing and the manipulations described will relieve back pain; e. g. side stretching of the spine is done while pressure is exerted on the second and the third lumbar and not below for fear that lumbosacral strain will be increased. Any one with a modicum of knowledge of the physiology of the spine knows that spinal movements are combined and that side counterpressure on the third lumbar will be transmitted to the lumbosacral junction. The exercises outlined on page 16 are known to most orthopedic surgeons and are simple, but the author is not definite about when they should be given or in what order, and there are no warnings about doing them too much or too long. One is left with the impression that this incomplete book should not be put in the hands of the general practitioner until he knows more about the general principles of physical medicine.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TECHNICS OF MASS IMMUNIZATION

To the Editor:—What technics in the sterilization of syringes and needles, the frequency of changing them and the use of topical antiseptics should be followed in mass inoculation of soldiers?

Rodney C. Larcom Jr., Captain, M. C., A. U. S.

ANSWER.—In consideration of the military necessity of carrying out required immunizations on large numbers of troops with as little interference with training and other duties as possible, it is necessary to adopt the simplest and most rapid procedure consistent with safety. The most careful aseptic technic must be exercised at all times.

The largest syringes are employed which will permit accurate measurement and delivery of the proper dose: 5 or 10 cc. syringes are usually satisfactory. These are initially sterilized by heat, filled with the vaccine or other immunizing agent and used until empty. The syringe may be refilled without resterilization if care is taken. The needle must be changed after each injection, a supply of freshly heat sterilized needles being kept on hand. If accidental contamination of the interior or tip of the syringe occurs or if blood enters the syringe, it should, of course, be discarded. Tincture of iodine, 70 per cent ethyl alcohol or an approved mercurial antiseptic should be used for skin sterilization, preceded by cleansing with soap and water if indicated. For smallpox vaccination, however, the arm should be prepared by washing with soap and water, ether or acetone and allowed to dry thoroughly before the vaccine is deposited on the skin; nonvolatile antiseptics, including alcohol, should be avoided, as they may inactivate the vaccine.

HEREDITY OF ALOPECIA AREATA

To the Editor:—Is alopecia hereditary? A woman 25 years old is bald except for a few patches of hair about an inch long. This alopecia began at the age of 7. What would be the probable result if she married and had children? There has been no family history of a similar condition.

M.D., Indiana.

ANSWER.—This patient has alopecia areata, the real cause of which is unknown. It is classed as a trophoneurosis due to some abnormality of the sympathetic nerves supplying the skin or its vessels; instances are commonly seen where there has been a preceding shock to the nervous system. It is most common in childhood and early adult life. "Sabouraud supplies the most convincing evidence that heredity plays a part, for he found that 22 per cent of 81 cases gave a history that other members of the family had the same disease. In Sabouraud's family groups six show a father and son affected, a seventh two brothers and the son of one of them. In one family a boy, his mother and the mother's brother and his maternal grandfather were all affected. In four families a generation is skipped: in one a boy and his father's brother had it, but his father escaped; in another a boy and his mother's brother had it but his mother escaped" (Cockayne, E. A.: *Inherited Abnormalities of the Skin*, London, 1933, Oxford University Press). A case in which there was evidence of the disease being inherited has never been seen by the writer. In view of the patient's family history, the chances of her offspring developing the disease seem small.

BLOOD LOST FROM TONSILLECTOMY

To the Editor:—I should like to know how much blood is lost during an average tonsillectomy under local and general anesthesia, and how this blood loss compares with some of the more common surgical procedures.

M.D., Illinois.

ANSWER.—A reasonably careful search of the literature has not revealed information dealing with quantitative losses of blood during tonsillectomy done under either local or general anesthesia. The blood loss must obviously vary depending on the method of operation, the surgeon and the individual case.

In general the blood loss is higher under general anesthesia than when a local anesthetic is used. This is due in the first place to the cerebral congestion caused by ether, which is the anesthetic most commonly used, and to the fact that some

vasoconstrictor, such as epinephrine, is commonly used in conjunction with the local anesthetic agent injected.

Those who do tonsillectomies know that occasionally the blood loss may be no more than a few drops. In other instances it may be 30 to 100 cc. or more, but the latter amount is probably not common.

During a herniotomy or appendectomy the blood loss may be 100 to 200 cc.; in hysterectomy the loss is much greater. These figures are casual estimates. A careful study would require weighing the actual amount lost. The only discussion of this in a related field is the careful work done by Lyman Richards on blood loss during adenoidectomy (Some Considerations of Adenoid Bleeding, *Ann. Otol., Rhin. & Laryng.* 44:117 [March] 1935).

SPLENOMEGALY AND ASCITES

To the Editor:—For about two years a woman aged 35 has complained of intermittent nausea, vomiting, weakness, sweating, abdominal pain and bloating. She has become anemic, but there is no history of jaundice, hemorrhages or ecchymosis. There is no history of malaria, and the family history is negative for any previous similar trouble. There has been a loss of 55 pounds (25 Kg.) in five months. On physical examination the findings, except for slight pallor, are a large firm mass in the left upper quadrant, moderate enlargement of the liver and a small amount of fluid, essentially negative. Blood pressure is 110/80, hemoglobin 72 per cent, red blood cells 3,950,000, white blood cells 5,800, polymorphonuclears 64 per cent, small lymphocytes 30 per cent, large monocytes 6 per cent, urinalysis negative. Fragility test of the red blood cells showed an initial hemolysis at 0.38 per cent and complete at 0.30 per cent, bleeding time three and one-half minutes, coagulation time four and one-half minutes. A chest x-ray was negative. A preoperative diagnosis of Banti's syndrome was made. The abdomen was opened through an upper left rectus incision and a general exploration done. The liver was large and mottled in appearance and seemed to contain a lot of colloid-like material. It looked something like tapioca or the cross section of a colloid goiter. There was a little serous fluid present and a huge spleen with little evidence of perisplenitis. It was removed without difficulty. At the hilus of the spleen were a number of smooth nodules which appeared to be large, dark lymph nodes or multiple accessory spleens. There was congestive splenomegaly with foci of fibrosis and angiomatous areas with some hemorrhage. The lymph nodes showed chronic hyperplastic lymphadenitis. The diagnosis was advanced congested splenomegaly and chronic hyperplastic lymphadenitis. The convalescence was characterized by a rapid pulse, considerable fever, diffuse bronchitis and the development of ascites. The patient is in fairly good condition at present. The kidneys and bowels are normal, the appetite is good. The ingestion of fluids is limited and there is no medication other than capsules of bile salts. After return from the hospital, tapings were instituted at weekly intervals and light fluid in 10 pound amounts recovered, but at this time tapings at four day intervals produce 15 pounds of milky fluid. Could you suggest any treatment to lessen the accumulation of fluid?

M.D., Utah

ANSWER.—Ascites of this type is assumed to be due to obstruction in the portal circulation. In Banti's syndrome this obstruction is sometimes relieved by splenectomy. The failure of the result here does not make the problem simpler. Ascites is often relieved (but not cured) by the administration of one of the mercurial diuretics. When the diuretic is preceded by a few days of administration of one of the acid-base salts, such as ammonium chloride, the fluid output may be enhanced still further. This may result in fewer tapings.

Surgical establishment of a circulation to bypass the liver may be considered. Theoretically this may be done by abrading the liver capsule or by suturing the omentum to the structures of the abdominal wall. Satisfactory results are problematic. For the liver cirrhosis itself high carbohydrate and high vitamin diets are advocated. If this is a true "Banti's syndrome," any treatment is only palliative.

BLOOD CLOTTING

To the Editor:—What is the significance of a blood plasma which coagulates even before the red cells? The plasma thickens and has the appearance of lipemia, although I do not think this is actually present. The patient has had Hodgkin's disease for eleven years.

M.D., Ohio.

ANSWER.—Since plasma coagulates and red cells do not, the inquirer probably wishes to know the significance of a pale clot as compared with the normal red clot in blood which has coagulated in a test tube. This phenomenon occurs whenever there is a rapid sedimentation of the erythrocytes, so that the red cells have time to separate out before coagulation starts. The clot is normally red merely because erythrocytes are trapped in the fibrin network which forms in the clotting process. If the red cells have sedimented before clotting begins, the supernatant plasma coagulates, giving rise to the so-called buffy coat. This phenomenon occurs in conditions associated with a rapid sedimentation rate; it is usually due to a high fibrinogen content of the blood plasma, although disturbances in the albumin-globulin ratio, or the appearance of abnormal globulins in the plasma, can also produce this effect occasionally.

ANEMIA AND HYPOPROTEINEMIA COM- PLICATING SEVERE PROTRACTED PNEUMONIA

TREATMENT WITH PENICILLIN—

ROLE OF SPECIFIC SUPPORTIVE THERAPY IN
RECOVERY

S. HOWARD ARMSTRONG JR., M.D.

ALBERT C. ENGLAND JR., M.D.

CUTTING B. FAVOUR, M.D.

AND

I. HERBERT SCHEINBERG, M.D.

BOSTON

In writing of the symptomatic treatment of pneumonia in THE JOURNAL in 1921, Means and Barach¹ stated that "the hope for a true curative treatment for pneumonia undoubtedly lies in the field of specific therapy. . . . it is our object while waiting for the . . . specific cure to consider . . . symptomatic treatment . . . in terms of morbid physiology."

The cases here reported are of significance not merely as cures of severe infections by the most recent and perhaps most powerful of specific antibacterial agents.² They are presented as instances wherein supportive therapy has appeared as important as the antibacterial in recovery from a clinical status which, although hitherto rarely seen in pneumonia, may occur with increasing frequency as specific agents permit prolonged survival in the face of infections otherwise rapidly fatal. Thus it remains relevant in the management of those pneumonias for which specific therapy is available "to consider symptomatic treatment in terms of morbid physiology."

REPORT OF CASES

CASE 1.—History.—A man aged 38, a painter, was admitted to the hospital for treatment of pneumonia and bacteremia due to pneumococcus type I which had failed to respond both to sulfonamide and to specific antiserum.

Following bronchopneumonia at 3, the patient was free of respiratory symptoms until the insidious development of a right lateral empyema at 30. After drainage (which yielded 50 cc. of pus containing *Staphylococcus aureus* and beta hemolytic streptococcus and disclosed a bronchopleural fistula), clinical recovery was rapid. The patient remained asymptomatic until the present illness.

Dr. Armstrong is Welch Fellow in Internal Medicine of the National Research Council.

From the Medical Clinic, Peter Bent Brigham Hospital, and the Department of Medicine, Harvard Medical School.

1. Means, J. H., and Barach, A. L.: The Symptomatic Treatment of Pneumonia, *J. A. M. A.* 77:1217-1223 (Oct. 15) 1921.

2. The penicillin was provided by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for clinical investigation recommended by the Committee on Chemotherapeutics and Other Agents of the National Research Council.

Although this illness began with a chill followed by persistent malaise, painless nausea and vomiting and fever as high as 105 F., blood culture was negative and evidence of respiratory disease absent until the fifth day, when cough, rusty sputum containing type I pneumococci and signs of consolidation of the right upper and middle lobes appeared simultaneously with recovery of type I pneumococci from the blood stream.

Immediately oral sulfamerazine³ (an initial 4 Gm. and thereafter 1 Gm. every eight hours) was administered and retained despite nausea. The next day the blood sulfamerazine level was 8.9 mg. per hundred cubic centimeters.

Because persistent bacteremia, increasing dyspnea and weakness suggested a poor response to chemotherapy, on the seventh day 300,000 units of type I antipneumococcus rabbit serum was injected intramuscularly, without apparent improvement.

When admitted to the hospital on the eighth day of his illness, the patient's temperature was 104.5 F., pulse rate 120 and respiratory rate 45. He was dyspneic and dehydrated. His cyanosis could be improved by administration of oxygen by the B. L. B. mask.⁴ The trachea was deviated to the right. The respiratory excursion, nearly absent on the right, appeared generally limited by a "chicken breast" deformity of the thoracic cage.

Both physical and x-ray examinations disclosed spread of the pneumonia to the right lower lobe. In addition, physical signs suggested further spread to the left lower lobe, although the left lung was as yet clear to x-ray. Multiple thoracenteses, both at the site of the previous empyema and in the regions of the right interlobar fissures, yielded no pus.

The subsequent management, charted in part in chart 1, may best be described under two headings: (1) bacteriologic course and therapy and (2) respiratory and metabolic course and therapy.

Bacteriologic Course and Therapy.—Although admission blood culture was negative, direct sputum examination⁵ showed type I pneumococci in large numbers, and the Francis test⁶ was negative. The sulfamerazine level was 9.5 mg. per hundred cubic centimeters.

In addition to an immediate 2.5 Gm. of sodium sulfadiazine, the patient received 450,000 units of type I antipneumococcus rabbit serum intravenously and 4 Gm. of sulfadiazine by mouth in the next twenty-four hours. The drop in temperature and the reversal of the Francis test which followed were only transitory.

Subsequent rises of temperature to 103 F. and of respirations to 58 were shortly followed by the finding of consolidation in the left lower lobe. The Francis test again became negative; direct sputum examination continued to show many type I pneumococci, though blood culture remained sterile. The sulfonamide level was 12.2 mg. per hundred cubic centimeters.

6. Francis, T., Jr.: The Value of the Skin Test with Type Specific Capsular Polysaccharide in the Serum Treatment of Type I Pneumococcus Pneumonia, *J. Exper. Med.* 57: 617-631 (April) 1933.

The patient had received a total of 750,000 units of antiserum.⁷ Therefore, on the tenth day of his disease, sulfonamide and serum were replaced by 240,000 units of penicillin⁸ per day by continuous intravenous drip. On the following morning and during the remainder of the course no pneumococci could be found on direct sputum examination. Blood cultures continued negative. Only as isolated colonies, twice in sputum cultures and once in a urine culture, did the organisms reappear. In each instance subsequent cultures were negative. On the thirteenth day the penicillin dosage was halved, on the seventeenth day the route was changed to the intramuscular, and on the twenty-second day the drug was stopped.

When cultured in para-aminobenzoic acid free⁹ tryptose broth a concentration of sulfadiazine of 10 mg. per hundred cubic centimeters failed to inhibit luxuriant growth of pneumococci derived from the patient's sputum, whereas concentrations of penicillin greater than 0.012 Oxford unit per cubic centimeter completely inhibited growth.¹⁰

Respiratory and Metabolic Course and Therapy.—However dramatic the apparent bacteriologic response, penicillin was followed by no immediate clinical response beyond the fact that gradual cessation of the previously progressive spread left the patient one functioning lobe. Cyanosis became deep even while the patient was at rest in an oxygen tent. The swinging

plasma and 3,330 cc. of whole blood. Uniform penicillin intake was attained by using blood and plasma as solvents. After partial correction of the patient's admission hypochloremia,¹¹ from 80 milliequivalents per liter to 89 milliequivalents per liter, sodium chloride intake was not permitted to exceed 10 Gm. a day, of which the greater part was intravenous. On this regimen chlorides were maintained between 90 and 96 milliequivalents per liter.¹²

During the first days of intensive blood and plasma therapy, hemoglobin and plasma proteins rose slowly from the initial low levels, and pulse, temperature and respirations remained high. Nevertheless the tendency to extreme dyspnea, cyanosis and pulmonary edema lessened. On the fourteenth day the first signs of clearing appeared over the right upper lobe and were confirmed by x-ray on the fifteenth day.

Toward the end of blood and plasma therapy, plasma proteins attained 6.3 Gm. per hundred cubic centimeters, hematocrit was 40 and the patient's condition appeared far less precarious. Within four days of the cessation of daily therapy, however, the hematocrit dropped to 35, the proteins to 5.6 Gm per hundred cubic centimeters. Pitting edema of the sacrum was first noted on the twenty-second day.

At this time, however, the slow process of clearing became manifest by a decreasing need for oxygen, the daily maxima of vital signs grew less (chart 1), and the patient began to eat. A period of severe distention, which failed to yield to the usual measures of poultice, rectal tube and pitressin, responded to additional vigorous neostigmine therapy, at one time attaining 2.5 mg. in five hours. In the ensuing twelve days, with increasing dietary protein intake, plasma proteins rose to 7.2 Gm. per hundred cubic centimeters. Simultaneously with the disappearance of clinical edema the patient lost 25 pounds (11.3 Kg.). His temperature remained normal after the thirty-second day; weight gain without edema began on the fortieth day.

When discharged on the forty-second day, muscular weakness and atrophy were striking. To x-ray examination, clearing of the chest was not yet complete; the sedimentation rate remained elevated at 53 mm. per hour. Examination of sputum and gastric washings for acid fast organisms, together with guinea pig injection, proved negative.

After five weeks at home, weight, muscle fullness and strength showed considerable improvement, and the sedimentation rate had reached a normal value of 10 mm per hour. The trachea remained deviated to the right; beyond evidence of right pleural thickening, the chest was clear to physical and x-ray examinations.

CASE 2.—A white man aged 85, whose first wife and 3 children had died of tuberculosis, gave no history of respiratory disease beyond a poorly remembered pneumonia fifty years previous to admission to the hospital for prostatectomy. For the past decade, gradually decreasing appetite abetted by poorly fitting false teeth had resulted in a steadily decreasing meat intake. In the year before admission, beyond a daily egg nog and an occasional small piece of pork, the patient's meals consisted principally of carbohydrates and tea.

Preoperative physical and x-ray examinations of the chest revealed moderate emphysema and a slightly enlarged heart. Fissures were present at the corners of the mouth. The

Chart 1 (case 1) — Partial clinical course, showing antibacterial, whole blood and plasma therapy

temperature attained 105 F. The ordinary maneuvers of nursing care and in 1 instance the inadvertent injection of about a liter of intravenous fluid in less than an hour precipitated attacks of extreme dyspnea and tachycardia (with rates exceeding 60 and 140 respectively) and the appearance of moist rales in the remaining lobe.

On the tenth day, during which the patient frequently appeared close to death, plasma proteins were found to be 4.5 Gm per hundred cubic centimeters and the hematocrit 30. Infusion of 250 cc. of plasma followed by 600 cc. of whole blood on the eleventh day was so closely paralleled by a fall in respiratory rate and by distinct relief of dyspnea (despite a simultaneous temperature rise) that between the eleventh and nineteenth days the patient was given a total of 3,550 cc. of

12. The patient's sodium intake exceeded that comprised by sodium chloride in that each liter of blood contains 3 Gm and each liter of plasma 8 Gm of sodium citrate as an anticoagulant.

tongue was red, geographic and smooth edged. Teeth were absent. The skin and gums were free of hemorrhage. A red scaly rash (said to be of six years' duration) overlay saphenous varicosities of the left lower leg. There was no edema. Both medial and lateral lobes of the prostate were enlarged. The remainder of the physical examination was irrelevant.

On the day after a well tolerated suprapubic prostatectomy the patient's condition appeared excellent. On the second postoperative day a cough productive of rusty purulent sputum and a rise of temperature to 103 F. (chart 2) were accompanied by the development of physical and x-ray evidence of consolidation in the right chest. Staphylococcus aureus was found on sputum culture.

Despite immediate administration of sufficient sulfadiazine to maintain blood levels between 7 and 12 mg. per hundred cubic centimeters the continued elevation of vital signs, the increasing dyspnea and the spread of the pneumonitis to the left chest led to replacement of sulfonamide by penicillin on the sixth postoperative day.

On an initial daily intravenous dosage of 240,000 units of penicillin, slow clearing of the pneumonia began. Although sputum decreased and no organisms were recovered from the blood stream, vital signs remained elevated. The patient was frequently irrational.

A pleural effusion, originally localized over the right upper lobe, was first tapped on the fourteenth postoperative day after a shift to the right base. Reaccumulation of fluid in the face of progressive clearing of the lung parenchyma necessitated a total of seven thoracenteses in the next ten days. Although no viable organisms were recovered by culture, because the first thoracentesis fluid showed a specific gravity of 1.020 and a few gram positive cocci on smear, a total of 120,000 units of penicillin was injected intrapleurally over five consecutive days.

On the second postoperative day, plasma proteins were found to be 4.2 Gm. per hundred cubic centimeters. In the ensuing ten days the administration of 2,750 cc. of plasma together with the whole blood subsequently detailed and 3,500 cc. of amino acids by mouth was followed by a rise of plasma proteins to only 4.8 Gm. per hundred cubic centimeters. During amino acid administration the patient's dietary intake, initially limited by anorexia to soup, milk, fruit juices and an occasional eggnog, became further curtailed by the development of nausea, vomiting and diarrhea such that on the fifteenth postoperative day all food by mouth was refused. Stool culture was negative. Amino acids (together with oral and parenteral preparations of the fat soluble vitamins, ascorbic acid and the B complex previously administered) were then stopped.

During the ensuing five days diarrhea subsided, appetite slowly returned and following the further administration of 1,500 cc. of plasma the plasma proteins were 5.4 Gm. per hundred cubic centimeters. By this time extensive clearing of the pneumonitis had occurred, fever was returning to normal limits and appetite permitted dietary intake to attain preoperative distribution and the resumption of supplementary vitamins. Four months following discharge, plasma proteins were 7.0 Gm. per hundred cubic centimeters.

A preoperative erythrocyte count of 3,500,000 and a hemoglobin of 9.5 Gm. per hundred cubic centimeters fell to 2,900,000 and 8.2 Gm. respectively by the second postoperative day. Administration of 900 cc. of whole blood in the next two days returned the red count and hemoglobin to preoperative levels. Eighteen hundred cc. of whole blood during the following week was required to maintain these levels (chart 2). The rise of the red count to 4,100,000 during the end of the clearing of the pneumonia was not accompanied by a change in hemoglobin. The discharge hemoglobin level of 9.5 Gm. per hundred cubic centimeters was identical with that on admission. The patient was put on 0.3 Gm. of ferrous gluconate three times a day. Four months after discharge the hemoglobin was 11.9 Gm. per hundred cubic centimeters.

COMMENT

Beyond the hemolytic anemia occasionally associated with sulfonamide administration,¹³ progressive anemia has not been widely recognized as a hazard in pneumonia.¹⁴ Likewise until the recent appearance of such values as 3.6 Gm. per hundred cubic centimeters reported in a prolonged sulfonamide treated pneumococcal infection complicated by bronchiolitis fibrosa obliterans,¹⁵ the plasma proteins in pneumonia have rarely been found lower than 90 per cent of the normal value. These previously reported changes are consistent in amount with the recently observed increases in plasma volume.¹⁶

The hypoproteinemia and anemia encountered at the onset of illness in case 2 may well have been related to the deficient diet over a prolonged period. To the disease itself can be attributed only a progressive drop in levels already low. The extent of involvement of pulmonary tissue by pneumonitis was not sufficient to lead to dangerous respiratory embarrassment, such that once progression was checked by intensive therapy.

Chart 2 (case 2).—Partial clinical course, showing antibacterial whole blood, plasma and amino acid therapy.

impaired oxygen capacity and diminished plasma colloid osmotic pressure did not contribute significantly to the respiratory picture. Had measures to check progression been neglected, it is quite possible that further decrease in hemoglobin below 8.5 Gm. per hundred cubic centimeters and plasma proteins below 3.3 Gm. per hundred cubic centimeters would have led to a different outcome in this 85 year old man.

In contrast to case 2, the history and physical appearance on admission in case 1 gave no basis to suspect either hypoproteinemia or anemia antecedent to the onset of his illness. Moreover, although penicillin and serum had effected apparent bacteriologic arrest, on the tenth day of his illness pulmonary involvement

was so extensive that he remained in desperate need of symptomatic treatment directed at morbid respiratory physiology.

That this is not an isolated experience in treating lobar pneumonia with penicillin emerges from Tillet's¹⁷ series of 46 cases wherein all three deaths followed bacteriologic improvement; in 1 "chronic pulmonary disease" was present; in another pulmonary edema developed.

It is therefore of interest to analyze in this case the interrelations of the chief factors underlying the deranged respiratory physiology and the methods available for their therapy:

1. *Therapy aimed at elimination of impediments to free movement of respiratory muscles:* In this case neither the thoracic deformity nor the anatomic sequelae of the previous empyema could be eliminated. However, had not moderate distention (of little danger to a patient with more functional lung tissue) responded promptly to vigorous treatment, progression of the elevation and limitation of motion of the left diaphragm alone might well have changed the outcome.

2. *Therapy of airway obstruction:* Because low viscosity helium-oxygen mixtures and bronchodilator-vasoconstrictor inhalation technics introduced by Barach and his co-workers¹⁸ have saved life when bronchial spasm or other obstruction has complicated pneumonia, these measures were held in readiness.

3. *Therapy directed toward attainment of high alveolar oxygen and maintenance of the remaining functional lung tissue in optimum condition for gas exchange:* Brief deprivations of oxygen demonstrated its indispensability many times during the critical period of minimal clearing. Administration by the mask designed by Barach and his associates¹⁹ for positive pressure expiration could probably have achieved better edema control²⁰ by opposition of controlled intra-alveolar pressures up to 50 mm. of water to fluid movement from capillaries to alveoli.

The attacks of edema in the single uninvolved lobe were of great danger. Moreover, the initial degree of hypoproteinemia indicated that plasma colloid osmotic pressure remaining to counteract edema due to any sudden increase in pulmonary intracapillary pressure was less than two thirds the normal value of approximately 300 mm. of water.²¹ The drop in plasma proteins following cessation of intensive plasma therapy suggests that had not the amount used (greater than the normal total circulating plasma proteins) been sufficient to counterbalance the progressive hypoproteinemia until clearing of pneumonia had begun, increasing pulmonary edema might have proved fatal.

4. *Therapy directed at maintenance of normal blood oxygen capacity:* Before clearing, anemia corresponded to a blood oxygen capacity approximately two thirds normal. Transfusions totaling almost two thirds the normal circulating red cell volume raised the hematocrit only from 30 to 40. The hematocrit drop following cessation of transfusions suggests that had not progressive anemia been thus counterbalanced the oxygen capacity of the blood reaching the remaining functional lung tissue might well have fallen low enough to negate the effects of other therapy.

Prevention of anemia and hypoproteinemia might well have made the course in this case less precarious. In that even anemia of slight degree may be of significance in widespread pneumonia, the obvious therapy is to anticipate development by transfusion.

The 40 Gm. of protein per day given in the week of plasma therapy provided this patient with 30 Gm. less than the protein requirement of a normal afebrile man whose total caloric intake is otherwise adequate.²² Nausea during the previous ten days of high fever kept both protein and caloric intake minimal and prevented administration by intubing tube of a nutritionally complete ration used with success by Olmsted and his associates²³ in typhoid. Thus the avoidance of hypoproteinemia in such severe pneumonia probably demands the use of plasma or amino acid mixtures²⁴ in massive amounts guided by plasma protein determinations well before the maximum spread has occurred.

SUMMARY

Severe and progressive anemia and hypoproteinemia developed in 2 cases of extensive and protracted bacterial pneumonia treated with penicillin. In 1 case anemia and hypoproteinemia of nutritional origin probably antedated the pneumonia; in the other no such presumption existed.

An increasing frequency of such cases is anticipated as powerful antibacterial drugs permit control of infections otherwise rapidly fatal.

In these patients enormous amounts of whole blood and plasma were required to counteract the progression of the anemia and hypoproteinemia. The fact that this therapy, together with nearly all known measures for maintenance of optimum gas exchange in remaining functional lung tissue, appeared necessary to maintain life for some time after apparent bacteriologic arrest of the infection suggests that, in pneumonias of this severity, development of anemia and hypoproteinemia should be anticipated by early use of whole blood and plasma together with adequate protein dietary intake.

Rise of Neurology in the Civil War.—Perhaps the outstanding medical event of the Civil War was the rise of the neurological profession in America. The Civil War is often regarded as parent, or at least nurse, to that infant profession. The four years of fratricidal strife also produced data on military psychiatry that might have proved valuable in future wars had their lessons not been so soon forgotten, only to be painfully relearned. Most interesting, perhaps, were the clinical observations of medical officers on such subjects as nostalgia and malingering among soldiers, together with notes on psychiatric screening in selective service.—*One Hundred Years of American Psychiatry*, New York, Columbia University Press, 1944.

THE USE AND ABUSE OF NASAL VASO-
CONSTRICTOR MEDICATIONS

BARNEY M. KULLY, M.D.

LOS ANGELES

No class of drugs is more widely distributed and used than are nasal vasoconstrictors. This is due to advertising of "patent" nostrums in press and radio, to exploitation of new compounds to the profession by pharmaceutical houses and to wide prescription of these drugs by physicians. Tabulation reveals that there are nationally distributed at least 240 nasal vasoconstrictor compounds in the form of drops, sprays, inhalants and ointments. It is timely to question whether the increased use of vasoconstrictors is justifiable and whether there are not disadvantages inherent in these drugs which demand a reappraisal of the indications for their use.

Since sympathomimetic compounds are the basis of nasal vasoconstrictor medication, this discussion is limited to their consideration. The first of these drugs to be isolated was the alkaloid ephedrine¹ in 1887. It was recovered from the herb *ma huang*, an old Chinese drug used empirically by Chinese physicians for over five thousand years. In 1895 Oliver and Schafer² demonstrated the active principle of the adrenal medulla, epinephrine. Since then these substances have been studied and their chemistry further clarified by Abel,³ Aldrich,⁴ Chen⁵ and others. Working independently, Stolz⁶ and Dakin⁷ in 1905 produced epinephrine synthetically. Five years later the studies of Barger and Dale⁸ led to the discovery of synephrin, neosynephrin and many allied compounds. Paredrine was introduced in 1913, propadrine in 1929, benzedrine (amphetamine) in 1930 and privityne in 1941. Several hundred additional compounds, allied chemically and therapeutically, have been synthesized and studied. Obviously, only a few have been employed in therapeutics.

PHARMACOLOGY

These drugs are adrenergic or sympathomimetic in action. They simulate the responses resulting from stimulation of the postganglionic nerves, but, as Goodman and Gilman⁹ point out, each drug differs in the details and intensity of the elicited responses. The cerebral stimulation of amphetamine, for example, is more pronounced than that of epinephrine. However, a discussion of the differences in systemic responses to these drugs is not within the scope of this paper.

The action of sympathomimetic drugs on the nasal mucosa is directed chiefly to the blood vessels, though the secretory function also is affected. Primarily the

effect on the blood vessels is vasoconstriction. The sub-epithelial capillaries and arterioles as well as the venous sinuses of the erectile tissues are constricted. Nasal secretion is diminished in contrast to the increased secretion that occurs when vasoconstriction results from chilling of the body surfaces.

If vasoconstriction is severe or prolonged, a reversal reaction ensues in the form of a secondary vasodilatation involving the deeper venous sinuses more than the sub-epithelial vasculature. This accounts for the fact that the mucosa remains blanched. The secondary reaction may be more evident and prolonged than the primary constriction.

Secondary vasodilatation is due either to an active vasodilator in the drug or to a fatigue of the constrictor mechanism. The active dilator of certain sympathomimetic drugs has been demonstrated in epinephrine in the so-called reversal phenomenon. If ergotamine or ergotoxin is injected into an animal in sufficient amounts, subsequent administration of epinephrine results not in vasoconstriction and increased blood pressure but in vasodilatation and lowered blood pressure. This reversal reaction has not yet been demonstrated in ephedrine or amphetamine, but Goodman and Gilman¹⁰ state that it is present in other sympathomimetic drugs.

The diphasic action of these drugs is premised on the experiments of Cannon,¹¹ who showed that stimulation of the sympathetic nerves results in the formation of a chemical mediator at the sympathoeffector junctions known as sympathin. This substance is chemically and pharmacologically related to epinephrine, the mother substance of the sympathomimetic amines. It may possess both excitatory and inhibitory components called sympathin E and sympathin I. Epinephrine combines both of these properties, the one constricting, the other dilating blood vessels. In epinephrine, the dilating factor has a more prolonged effect than the constricting factor. When constriction subsides, the inhibitory sympathin I remains unopposed to produce vasodilatation.

The fatigue factor as a cause for secondary vasodilatation may be based on exhaustion of the sympathin constricting factor or may be a physiologic reaction to overstimulation of the vasopressor mechanism. The clinical fact remains that persistent vasoconstriction results in secondary dilatation. When this occurs the mucosa becomes increasingly less responsive to subsequent applications of vasoconstrictor drugs.

FACTORS AFFECTING SECONDARY VASODILATATION

The degree of this after-dilatation is dependent chiefly on the type and amount of the sympathomimetic drug used and on the susceptibility of the individual vasomotor mechanism. To a lesser extent it is dependent on the pH of the drug, its vehicle, the presence of irritating compounds and the effect on the ciliary mechanism.

Sympathomimetic drugs vary in the intensity and the duration of the primary constricting effect and in the severity of their secondary dilating effect. Epinephrine and amphetamine are examples of drugs causing severe reactions, ephedrine and neosynephrin represent those producing a milder reaction. In my clinical experience none of the adrenergic drugs are free from this second-

dary congesting effect. The statements of manufacturers that the newer vasoconstrictors cause no after-congestion are not in accordance with clinical findings. The amount of secondary congestion is proportionate to the intensity of the vasoconstriction, the frequency with which the drug is employed and the period of its use.

Individuals vary in their susceptibility to secondary reactions, but no one is completely immune. In many years of observation I have not seen a single patient who used any of these drugs to excess and remained free from the typical after-congestion.

Recent investigation shows that the p_H is a factor in the effect on the nasal mucosa. Fabricant¹² states that the p_H should approximate that of the nasal mucosa, 5.7. Other investigators report the reaction more nearly neutral. Significant variations in either direction are irritant and increase after-congestion. I have found, however, that even a neutral p_H does not preclude irritant properties.

In recent years there has been a tendency to incorporate antiseptics with vasoconstrictors. This is particularly true of the sulfonamides, which have been added to almost every type of vasoconstrictor. Sulfathiazole has appeared in at least thirty such combinations recently. The rationale of the use of antiseptics is questionable. They are in contact with limited areas of the nasal mucosa and then for brief periods of five to fifteen minutes. As shown by Walsh and Cannon,¹³ they do not penetrate into the subepithelial tissues where the infecting organisms thrive. They increase irritation and reaction. In my experience sulfathiazole combinations have been prime offenders, causing severe after-congestion. These observations have found confirmation in the work of Futch,¹⁴ who demonstrated that 5 per cent sodium sulfathiazole solutions have a caustic effect on the nasal mucosa, destroying cilia and superficial columnar cells. Fletcher¹⁵ reported necrosis of the mucosa of the maxillary sinus following irrigation with 10 per cent sodium sulfathiazole solution. The alkalinity of the solution is not the major factor, for even in buffered combinations where the p_H approaches neutral severe after-congestion occurs. I have been unable to substantiate the lavish claims of certain manufacturers that sulfathiazole vasoconstrictor compounds are valuable adjuvants in the treatment of acute rhinitis or of acute or chronic sinusitis.

The use of vasoconstrictors in the form of inhalants has become popular in recent years. Of these, amphetamine evokes the most vicious reaction because of its powerful pressor action and the ease of self administration. Reactions equally severe are caused by some of the "patent" inhalers. Adrenalin inhalant 1:100, though often affording spectacular relief to the asthmatic, is a powerful irritant to the nasal mucosa. When its use is necessary, the nostrils should be plugged with cotton to prevent the epinephrine saturated expired air from coming in contact with the nasal mucous membrane.

Vasoconstrictors in oily mediums are less irritant than those in aqueous solutions because the former are less efficient. Oils are not miscible with the overlying mucous sheet and by their inert weight interfere with

ciliary function. There are increasing reports¹⁶ of pneumonic complications following the intranasal instillation of oil, and in all probability many more cases occur than are reported. There is little justification for the continued use of oily mediums in the nose.

The effect on the ciliary mechanism of nasal vasoconstrictor medication has been studied by Proetz,¹⁷ Lierle and Moore¹⁸ and others and need not be here repeated. Disturbance in ciliary function and secondary vasodilatation are frequently coexistent, as proved by the action of epinephrine. Cocaine, on the other hand, is toxic to the ciliary mechanism but is less likely to produce secondary reaction. The danger of addiction, however, limits its use to surgery or to the acute emergency. The prescription of cocaine drops or sprays for use over a period of time is definitely unwise.

INDICATIONS FOR USE OF VASOCONSTRICTOR DRUGS

In nasal surgery, vasoconstrictor medication is a requisite. Bleeding is controlled, the field of vision widened and absorption of the anesthetic delayed. The use of a drastic vasoconstrictor, epinephrine, is justified, though postoperative swelling may be due more to the drug than to the surgery. Vasoconstriction is necessary in many manipulative procedures, such as sinus irrigations. In the displacement method of Proetz it is invaluable for therapy or visualization. Yet there has been observed damaging after-congestion with involvement of previously uninvolved sinuses, following too frequent displacement treatment or the use of drastic medication.

VASOCONSTRICTOR MEDICATION IN ACUTE RHINITIS

The value of vasoconstrictor therapy for acute rhinitis is questionable. The distress of the patient is temporarily relieved, justifying, in some instances, careful and minimal use of a mild decongestive drug. Unfortunately, such care is rarely exercised and the result is a disturbance in the nasal defense mechanism.

The nasal mucosa responds to infection, as do other body tissues, with swelling, augmented blood supply, increased exudation and diapedesis of cells. Shrinking the tissues with medication reverses this physiologic response. In no other tissue of the body is infection treated by diminishing the blood supply and shrinking the collateral edema. Such treatment lessens neither the severity nor the duration of the infection. On the contrary, the typical course of an acute rhinitis may be altered and prolonged. In the usual sequence the secretion, at first watery, becomes thick and mucopurulent between the second and third days. With this transition, nasal obstruction lessens. However, when the use of constrictive drugs results in after-congestion the mucosa assumes the gray edematous appearance of a vasomotor rhinitis. The obstruction persists and the secretion remains thin, often excoriating the nasal vestibula. Further medication gives temporary relief, soon to be followed by increased congestion, thus initiating a vicious circle. Persistence of watery secretion and nasal obstruction beyond the third day of an acute rhinitis signifies improper use of medication.

This misuse of medication prolongs the acute rhinitis and may cause sinus and otitic complications. A persistent vasodilatation with its edematous membrane may obstruct the sinus orifices and predispose to sinusitis. A study of my records shows that in a series of 640 patients with acute sinusitis 85 per cent had used some form of nasal vasoconstriction for three or more days prior to the onset of sinus symptoms. In each instance some degree of vasomotor rhinitis was noted. This does not prove that the drugs are causative, but the coincidence is suggestive. That they were a factor is indicated by the frequency with which the condition subsided spontaneously when medication was discontinued. I have seen instances of apparently intractable subacute sinusitis resolve when the mucous membranes were permitted to resume their normal functions.

It is not implied that nasal vasoconstrictors are contraindicated in the treatment of acute sinusitis. To shrink carefully the swollen mucosa about the orifice of an acutely infected sinus is a rational procedure. However, the margin between therapeutic shrinking and that of after-dilatation worse than the original condition is not a wide one and demands conservative judgment.

Otitic complications may follow the secondary reaction from vasoconstrictor drugs. Congestion about the eustachian orifices or the entrance of drops into the middle ear itself may be predisposing factors. In this connection Dintenfass¹⁹ reports a case in which, on myringotomy, mild protein silver previously instilled into the nose was found in the middle ear cavity. In a series of 64 cases of acute serous otitis media there was an associated use of nasal vasoconstrictor medication in 88 per cent. I have found the association of fluid in the middle ear and the secondary dilatation of nasal vasculature so frequently that I believe it to be significant. In 30 cases of acute suppurative otitis media, drops and sprays had been used in 14. This is a formidable ratio.

The use of shrinking medications for the relief of chronic obstruction due to hypertrophic rhinitis, septal deflections or nasal allergies has offered a fertile field for the exploitation of the vast gamut of vasoconstrictor drugs. Patients with chronic obstruction, especially those with allergic rhinitis, are rarely without their drops and inhalants. Many with vasomotor rhinitis who have received injections of allergens for years are sensitive chiefly to their nasal medication. The nasal symptoms and the need for injections would disappear if the medication was to be discontinued. The vasomotor rhinitis produced by drugs is identical with that due to allergy both in appearance and in the presence of eosinophils in the secretion. The following case report is extreme but instructive:

Mrs. M. B., aged 45, first seen in March 1940, had suffered from nasal obstruction, sneezing and watery discharge of many years' duration. Thirty years previously the diagnosis of allergic rhinitis was made and desensitization by injections initiated. For thirty years the patient had received one or more injections weekly. During this period nasal medications of all types had been regularly employed. The patient was persuaded to discontinue nasal medication and allergic injections for a four week trial period. At its termination she was free from nasal symptoms and has so remained.

It is difficult to induce patients to discontinue the use of nasal vasoconstrictors after long periods of self medication. It is a habit the breaking of which requires much persuasion and understanding on the part of the

physician. Many patients cannot sleep without their drops or inhalants, and these will for brief periods require sedation in the form of barbiturates or bromides.

Not all cases of vasomotor rhinitis are due to medication. Many are generally allergic and should be so treated. All, however, are aggravated by the use of shrinking drugs. The relief is temporary and the aftermath is increased obstruction. Persistent use of vasoconstrictors can produce progressively severe vasomotor rhinitis highly resistant to further applications of decongestant drugs. The end result may be a vasomotor paralysis.

The use of vasoconstrictor medication is not indicated in the treatment of obstruction due to adenoids, septal deviation, hypertrophic rhinitis, nasal polyps, neoplasms and so on. Such drugs are never curative and ultimately superimpose an additional congestion on the obstructive pathologic condition already present.

SUMMARY

1. A revaluation of the increased use of nasal vasoconstrictor medication is indicated.
2. The primary vasoconstricting effect of sympathomimetic drugs is usually followed by secondary vasodilatation.
3. This secondary vasodilatation is influenced mainly by the type and amount of the drug employed and the sensitivity of the individual vasomotor mechanism.
4. The addition of antiseptics, particularly sulfathiazole solutions, to vasoconstrictor drugs increases the irritant properties without compensatory therapeutic benefits.
5. Judicious use of vasoconstrictive medications is indicated in surgical, manipulative and displacement procedures and in some acute nasal infections, notably acute sinusitis.
6. The indiscriminate use of this medication in acute rhinitis lengthens the course of infection and increases the incidence of sinus and otitic complications.
7. Vasoconstrictor drugs may of themselves produce a vasomotor rhinitis indistinguishable from that due to allergy. Vasomotor rhinitis, allergic in origin, is made more severe by constricting medication.
8. The use of vasoconstrictor drugs in chronic obstructive pathologic conditions adds the factor of secondary congestion to the obstruction already present.

3875 Wilshire Boulevard.

ABSTRACT OF DISCUSSION

DR. LAWRENCE R. BOIES, Minneapolis: Any local treatment introduced into the nose in an acute rhinitis has little therapeutic value. Recent experience with the sulfonamide drugs incorporated into vasoconstricting drops or sprays, or the use of a sulfonamide in the powdered form, has not changed my ideas relative to the ineffectiveness of local therapy. I use mild vasoconstrictors in the acute phase of a rhinitis only to make the patient more comfortable and not with the idea that I am effecting a cure by this medication. In a subacute phase when the discharge has thickened, indicative of localization, there seems to be some indication that a conservative use of mild vasoconstrictors hastens the recovery. A certain amount of sinusitis invariably exists in an ordinary acute rhinitis. Local applications of tampons soaked with 15 per cent mild protein silver in equal parts of glycerin and water to the middle meatus or above the middle turbinate, or both, seems to be effective in the subacute stage of the infection. I do not use this treatment more often than every other day and rarely employ it for more than three or four times. Displacement therapy, as originated by Proetz, has been a useful treatment in the subacute phase of the infection. I avoid its use in the acute stage of the disease.

19. Dintenfass, Henry: *Otolaryngologic Suggestions in Pediatric Practice*, Pennsylvania M. J. 42: 226-230, 1938.

The average layman who medicates his nasal congestion because of the advice he has had over the radio is apt not to have an infection at all but rather a vasomotor state related to some dietary indiscretion, chilling of the body surface or excessive fatigue. These are transient states which often are over in three or four days. The victim often resorts to the use of nose drops and believes that the stronger vasoconstrictors containing aromatics and more recently the sulfonamides are the more effective. Too many medical men are still imbued with the idea that a stuffy nose or chronic headache must mean an independent disease of the nasal fossae or sinuses, or both.

DR. O. E. VAN ALYEA, Chicago: The present status of vasoconstricting nose drops is, in my opinion, as follows: 1. In the early stages of engorged tissues they are of little value except as a temporary expedient in lessening the discomfort of an acute head cold. 2. They are of no value in chronic sinusitis except as a vehicle in displacement therapy. 3. In subacute sinusitis they may prove helpful in removal of exudate from the sinuses. This is accomplished not only by the enlargement of the drainage space but through improvement in nasal breathing, which promotes the withdrawal of secretions by the negative pressure associated with inspiration. 4. Sulfonamide preparations are of no proved value intranasally and may be irritating and damaging to the ciliated mucosa. Although, in the main, agreeing with Dr. Kully, I find that in certain phases of his clinical observations our experiences have been somewhat at variance. I have not noted that complications of an acute nasal infection are more prevalent in those cases in which vasoconstrictors have been used, nor have I observed that the use of nasal decongestants prolonged to any appreciable extent the duration of a nasal infection. I have also seen cases of sinusitis and otitis which developed soon after the onset of a cold in which no medication whatever had been used. Dr. Kully rightly questions the feasibility of shrinking swollen membranes which are merely undergoing a normal physiologic response to disease. The same relief may be attained by an almost continuous baking under an infra-red lamp. This increases the swelling in the nose, which seems to be desirable. It also augments the blood supply, which steps up the physiologic response to the disease. The immediate comfort of the patient is due to the heated air, which as it is inhaled is no longer irritating but soothing to the nasal mucosa. Patients receiving this form of treatment feel no need of nose drops and none should be given. The principal users of nose drops in treatments of an acute rhinitis are those individuals who haven't the time or inclination to stay home and take care of themselves. There are often occasions when a patient with an acute cold must keep an important engagement. He needs something to lessen his discomfort, and this can be supplied most effectively in the form of an ephedrine-saline solution.

DR. BARNEY M. KULLY, Los Angeles: Most of us have been conditioned to the use of vasoconstrictors and we use them without due consideration. Our patients demand them for the temporary relief secured. When the after-congestion does occur, we ascribe it to the original infection for which the treatment was used and not to the medication. Many of the supposed one day cold cures with vasomotor compounds are not cures of colds but of temporary vasomotor conditions due to emotional upsets, dietary indiscretions and the like. In answer to Dr. Van Alyea, I did not advocate the complete cessation of the use of vasoconstrictor compounds. I stated that in acute colds, acute sinusitis and in the displacement treatment careful use was justifiable. These compounds must not be used beyond the point where a vasomotor rhinitis ensues. If a patient with an acute rhinitis has a grayish blue membrane, watery secretion and sneezing on the third, fourth or fifth day of the infection, one is justified in inquiring what vasoconstrictor compound is being used. My purpose was to call attention not only to the use of vasoconstrictors by rhinologists but to the vast use of these drugs by the public. The newspapers and radio advertise them, think it is up to us as rhinologists to educate the public that inherent in these drugs are harmful effects as well as benefits.

SENSITIVENESS OF MENINGOCOCCI
TO THE SULFONAMIDES

RAPID EFFECT OF ADMINISTRATION OF TWO GRAMS
OF SULFADIAZINE ON CARRIERS OF NEISSERIA
INTRACELLULARIS (MENINGOCOCCUS)

MAJOR ISADORE PILOT

MEDICAL CORPS, ARMY OF THE UNITED STATES

Among the gram negative bacteria, *Neisseria intracellaris* appears to be particularly sensitive to the sulfonamides. In active cases of epidemic meningitis the numerous organisms in the blood, spinal fluid and nasopharynx fortunately disappear rapidly as soon as therapy is instituted. In my experience the nasopharyngeal cultures usually are negative twenty-four hours after the administration of sulfadiazine either orally or intravenously.

The remarkable effect of sulfadiazine on *N. intracellaris* has been utilized by giving prophylactically two or more doses of 2 Gm. to contacts of active cases

and to inductees beginning basic training. In the spring of 1943 the administration of 2 Gm. of sulfadiazine daily for two days to 700 men resulted in substantial reduction in the number of cases of meningococcic meningitis during an epidemic period.¹ The result had been a striking check of the spread of meningitis by the elimination of most of the carriers and a pronounced reduction in the incidence of meningococcic infections.

Lewis, Bolker and Klein² in February 1943 instituted mass prophylactic treatment to civilian and military personnel by the administration of 6 Gm. of sulfadiazine, two doses of 2 Gm. daily for two days and then two doses of 1 Gm. each on the third day. New cases of meningitis did not appear, and the carrier rate dropped to 0.14 per cent.

The percentage of carriers depends on the number and frequency of cultures made of the nose, throat and nasopharynx of individuals. In the literature the carrier rate is quite variable. For our purpose a single culture

2. Lewis, W. B.; Bolker, H., and Klein, D.: Mass Treatment with Sulfadiazine: Its Effect During an Outbreak of Meningococcus Meningitis, *Mil. Surg.* 93: 443-447 (Dec.) 1943.

of the nasopharynx was made on a group of soldiers and a group of civilians who were being inducted. The swabs were immediately inoculated by streaking fresh blood agar plates made up of brain-heart-infusion agar (Difco) with packed human blood cells added in 5 per cent proportion. The plates were incubated in a carbon dioxide jar for twenty-four to forty-eight hours. On this medium *N. intracellularis* grew well, forming smooth, moist, translucent colonies often in predominant numbers in the persistent carriers. The organisms were readily isolated and with antisera identified and classified as type I, II and IIa.

During the spring of 1944, from single nasopharyngeal swab cultures of 28 soldiers, 6 (21.4 per cent) positive cultures for *N. intracellularis* were obtained, 2 type I, 2 type II and 2 type IIa. By a similar method a single culture of civilian inductees taken immediately on arrival from the train yielded 5 positives of 25 (20 per cent), 2 type I, 1 type II and 2 type IIa. Apparently the civilian carrier rate is approximately the same as that of army personnel.

Four carriers among laboratory personnel were studied at frequent intervals to note the effect of the single oral 2 Gm. dose of sulfadiazine on the nasopharyngeal flora. Cultures were made immediately before administration and at two, six, twelve and twenty-four hour intervals after taking the drug. Blood sulfadiazine levels were made on the same persons two, six, twenty-four and forty-eight hours after the medication.

The changes in the incidence of *N. intracellularis* of the nasopharynx were noted quantitatively on the blood agar plates (table 1). In two hours no changes were observed, in six hours the number of colonies of *N. intracellularis* dropped considerably, in twelve hours the colonies were few and in twenty-four hours and subsequently they were absent.

Noteworthy was the effect of the sulfadiazine on the total flora of the nasopharynx. After six to twelve hours the decrease in number of colonies varied from 25 per cent to 50 per cent and remained depressed for twenty-four hours more. In three to five days the flora gradually returned to previous numbers except for *N. intracellularis*. Incidental pneumococci and the few hemolytic streptococci encountered were not influenced by the therapy.

No untoward effect or reactions were observed in the carriers as the result of the administration of the sulfadiazine.

The free sulfadiazine blood levels were determined in the 4 carriers at varying intervals (table 2). In the two and six hour samples the blood reached the highest level, varying from 2.8 to 4.8 mg., then declined in twenty-four hours and was almost free in forty-eight hours.

Two additional soldiers, carriers of type I, were subsequently treated by the 2 Gm. dose of sulfadiazine. One remained negative for a week, left the post and returned in thirty days when his cultures were again positive, but on typing the strain at this time belonged to type II. The other carrier was a heavy soldier weighing 220 pounds (100 Kg.). His blood level reached only 1.2 mg. The nasopharyngeal cultures, however, remained negative for eleven days after therapy and then again became positive for type I. A larger single dose of 4 Gm. of sulfadiazine was given. His blood level with this dose reached 5.1 mg. per hundred cubic centimeters and *N. intracellularis* again rapidly disappeared from the nasopharynx.

The present series is too small to justify the drawing of any conclusions. Further studies are necessary to determine the causes of the return of the carrier state. Inadequate dosage may be the most frequent factor when the single dose of 2 Gm. is given without regard to body weight. Under crowded conditions reinfection may reestablish quickly the carrier state by introducing other strains of *Neisseria*. However, local factors such as infections of the nose and accessory sinuses should be investigated in instances in which the same type or another type of *N. intracellularis* persists or recurs repeatedly.

SUMMARY

Carriers of *N. intracellularis* given a single dose of 2 Gm. of sulfadiazine rapidly become free of these organisms in nasopharyngeal cultures in twelve to twenty-four hours. The carrier state may return by the appearance of another type of *N. intracellularis* or of the same type if the dose is not adequate.

ASEPTIC NECROSIS OF THE EPIPHYSES AND SHORT BONES

ROENTGEN STUDIES

HOWARD P. DOUB, M.D.

DETROIT

Areas of necrosis involving the epiphyses and also the primary centers of ossification in certain of the short bones have been described by different observers. Unfortunately in most instances the lesion has come to be known by the name of the original observer. This has the disadvantage of giving no hint as to the underlying pathologic process and, further, of implying that in each instance we are dealing with an independent disease which bears no relation to the others in the series. These diseases have been known also under more general headings such as epiphysitis, osteochondritis and subchondral necrosis. It is now generally accepted that they all represent the same underlying pathologic process, although there is no general agreement as to the exact etiologic agent.

ETIOLOGY

Several theories have been advanced to explain the occurrence of areas of necrosis in the short bones and epiphyses. Endocrine dysfunction has been suggested. Infection has been demonstrated at the time of operation in a number of cases, but certainly this is not true in the vast majority, while clinical evidence of infection is minimal or, for the most part, nonexistent. A history of trauma is often obtained, and many authorities have leaned strongly toward this as the etiologic agent. There is, indeed, supporting evidence for the traumatic theory in certain cases. It is well known that aseptic necrosis of the capital epiphysis of the femur may ensue after closed reduction of a congenital dislocation of the hip and may closely follow the usual course of osteochondritis deformans juvenilis. In most examples of Osgood-Schlatter's disease of the tibial tuberosity there is a history of previous injury and, in Freiberg's necrosis of the metatarsal, trauma of some degree is associated with nearly every case. Those who advocate the traumatic theory are divided as to the pathologic changes

involved. Many believe that a vascular occlusion is produced by the trauma, shutting off the blood supply to the involved epiphysis, with subsequent necrosis. Others attribute the necrosis to an embolic vascular occlusion.

PATHOLOGY

Because of the nature of the disease, which is usually mild and self limited, there is a scarcity of pathologic reports based on biopsy material. The general trend in recent years, however, is to consider these lesions under the heading of aseptic necrosis. This is largely due to the work of Axhausen, who believed that there is actual death of the ossifying nucleus of the developing epiphysis or short bone. This is followed by fragmentation, irregular absorption and finally replacement by means of so-called creeping substitution or recalcification.

Phemister¹ states that in children aseptic necrotic bone is nearly always completely replaced by new bone and that the replacement proceeds more rapidly than in adults. He adds that, as a result of pathologic studies, it has been learned that in necrosing lesions of the

frequently obtained, but not with sufficient constancy to establish it as an etiologic factor. The disease is usually unilateral but may involve both femurs.

Pain is often the first symptom and may be referred to the knee. Limping is a cardinal sign. There is always some limitation of motion, particularly of outward rotation of the femur. There may be muscular atrophy and a feeling of thickening of the periarticular structures. The symptoms may at first be inconstant and frequently disappear with simple rest in bed.

The roentgen picture is diagnostic when the lesion is well developed. It varies considerably in the different stages of the disease, thus affording an index as to the progress of the degenerative and reparative processes. The earliest stages are seen infrequently, but Waldenström² reports cases in which the only change present was a slight flattening of the capital epiphysis. This was shown to much better advantage in the lateral view, since it was the upper anterior portion of the bone which was necrotic. Occasionally also there is a very thin faintly distinguishable line concentric with the superior border of the epiphysis, indicating the chondro-

epiphyses during the growth period the cartilage may show evidences of nutritional disturbance in places, but in large part it remains alive and may become thicker than normal, taking part in further epiphysial growth after the necrotic bone has been replaced.

CLINICAL SIGNS

The clinical signs of aseptic necrosis will not be described here in detail, but some reference will be made to them in the description of the disease as it manifests itself in various locations. Usually there is a history of mild or moderate pain, with limping if the involvement is in a weight bearing area. The patient is not acutely ill, and often there is no other complaint. The involved area is tender to palpation, and there may be restriction of normal motion. When the spine is involved, there is usually an accentuation of the dorsal curve.

OSTEOCHONDRITIS DEFORMANS JUVENILIS, OR LEGG-PERTHES DISEASE

Osteochondritis deformans juvenilis—so-called Legg-Perthes disease—affects the femoral head in children between the ages of 3 and 12 years. It is predominantly a disease of boys, and a history of trauma is

osseous junction, with subchondral bone resorption beneath it.

Gill,³ on the other hand, is of the opinion that the earliest changes occur in the metaphysis of the neck of the femur, consisting of areas of decalcification. These vary in number and size and tend to coalesce to form a broad band across the entire metaphysis. In our cases I have usually found a simultaneous involvement of the epiphysis and metaphysis. This often consists of an area of slightly lessened density near the outer margin of the capital epiphysis and the adjacent area of the metaphysis.

As the lesion progresses there is a concomitant necrosis of the capital epiphysis and the adjacent metaphysal area. Fragmentation often occurs, with patches of decalcification and sometimes isolated areas of increased density in the epiphysis. The epiphysial decalcification may proceed until only fragments of calcific material remain. In other cases the epiphysis is compressed and flattened but correspondingly widened in its lateral diameter. This stage of degeneration usually runs about eighteen months, but the period will vary somewhat according to the presence or absence of adequate therapy.

3. Gill, A. B.: Legg-Perthes Disease of the Hip: Its Early Roentgenographic Manifestations and Its Cyclical Course, *J. Bone & Joint Surg.* 22: 1013-1047 (Oct.) 1940.

1. Phemister, D. B.: Changes in Bones and Joints Resulting from Interruption of Circulation: General Consideration and Changes Resulting from Injuries, *Arch. Surg.* 41: 436-472 (Aug.) 1940.

In the stage of recovery there is slowly beginning recalcification, with disappearance of the fragmentation. The dense islets are no longer seen, and a more uniform new bone formation occurs in the usual area of the capital epiphysis. In many cases the metaphyseal lesions become recalcified earlier than those in the epiphysis. In cases with adequate treatment the stage of recovery usually extends over a period of two or three years.

The end result in most cases is a flattened head and widened neck of the femur. The acetabular cavity shows plastic changes, accommodating itself to the shape of the femoral head. In cases in which there has been a complete absence of weight bearing during the entire course of the disease, there may be an almost perfect restoration of the normal size and shape of the femoral head.

The etiology of Legg-Perthes disease has never been definitely established, but the general opinion is that it represents an instance of primary aseptic necrosis of bone. This is probably the result of a shutting off of the blood supply to the involved area, though the cause of the block is not definitely known. The fact

tion. The disease is characterized by weakening of the bond between the capital epiphysis and the metaphysis, with subsequent displacement of the epiphysis posteriorly and inferiorly.

The condition has been attributed to endocrine dysfunction, trauma, osteomalacia, late rickets and other conditions. No one of these, however, has been proved to be consistently present. It is possible that the rapid growth at this period together with obesity and the physical activity characteristic of this age group may play an etiologic role.

These patients often complain of intermittent pain and stiffness in the knee and thigh and have a noticeable limp. Fatigue is a prominent feature. There is limitation of internal rotation and abduction of the femur.

All motions except extension are limited. After slipping of the epiphysis has occurred, the symptoms and signs usually become more pronounced. Shortening may also be present. Symptoms may be manifest before any demonstrable displacement of the capital epiphysis has taken place, and it is in these cases that

Fig. 4 (case 1).—Four months later. Necrosis with fragmentation of capital epiphysis. No reparative process visible.

Fig. 5 (case 1).—Seven and one half months later. Evidence of early recalcification in capital epiphysis indicative of reparative stage.

Fig. 6 (case 1).—Nine months later. Extensive recalcification of epiphysis, showing continued improvement.

that similar decalcification and fragmentation of the capital epiphysis sometimes develop after closed reduction of a congenital dislocation of the hip suggests that trauma to the blood supply may be the cause of this group of cases.

CASE 1.—J. L., a white boy aged 6 years, had been limping for the past month. He had had intermittent pain in the left leg and on one occasion was not able to walk home from school. In addition to the mild limp on the left side, examination showed limitation of complete abduction and also of internal and external rotation.

Roentgenograms revealed very early bone changes with irregular bone density in the head of the left femur, along the lateral margin of the capital epiphysis and also the metaphysis. These changes, together with the clinical findings, suggested early Legg-Perthes disease (figs. 1 and 2).

The boy was treated by means of a walking caliper and restriction of activity, since complete inactivity could not be enforced. The fragmentation and necrosis became rather extreme, but in slightly over two years there was pronounced recalcification of the head of the femur (figs. 3, 4, 5 and 6). There was a residual flattening of the capital epiphysis, with thickening of the neck of the femur (fig. 7).

SLIPPING OF THE UPPER FEMORAL EPIPHYSIS

Slipping of the upper femoral epiphysis occurs during early adolescence, usually between the ages of 10 and 16. There is no important difference in sex distribu-

a heavy responsibility rests on the roentgenologist to recognize what is sometimes spoken of as the preslipping stage.

In this early stage the roentgen changes consist of varying degrees of decalcification of the portion of the metaphysis adjacent to the epiphysal line, which thus appears widened and irregular. This is often seen to

Fig. 7 (case 1).—Eleven months later. Residual flattening of head of femur and thickening of femoral neck.

better advantage on films made with the leg abducted and externally rotated and is especially noticeable on comparison with the normal hip.

After slipping has taken place there is anteversion of the neck in relation to the epiphysis, followed by

upward displacement so that the epiphysis lies posteriorly and inferiorly. The true relations are again demonstrated to better advantage in the semilateral view. Callus may occasionally be seen, depending on the stage of the disease. When treatment has been successful, there is usually complete ossification of the epiphysal line. In cases in which structural deformities persist, arthritic changes are likely to be present in later life.

Fig. 8 (case 2).—The anteroposterior view shows the head and neck of the femur with very little evidence of abnormality. The lateral view indicates slight widening of the epiphysal line and beginning decalcification in the metaphysis.

CASE 2.—S. K., a white girl aged 12, was seen one week after the onset of pain in the right hip. The pain was noticed after walking some distance, but there was no history of injury. Examination disclosed slight limitation of internal rotation of the leg but no other abnormal changes. Roentgenograms were negative. Early slipping of the upper femoral epiphysis was suggested by the clinical examination.

The patient was put to bed for three weeks but continued to have discomfort in the hip. She had a low grade fever during this period. A slightly irregular calcification was now demonstrable in the metaphysis of the femur just back of the epiphysal line, but there was no displacement of the epiphysis (figs 8 and 9).

Under continued observation at frequent intervals the patient appeared to improve clinically but showed little change roentgenographically. Four months after the first observation, however, the symptoms flared up and roentgenograms revealed

Fig. 9 (case 2).—Lateral views of both hips, showing early changes around the epiphysal line of the right femur.

definite evidence of slipping of the capital epiphysis. This was seen in the lateral view of the hip. The anteroposterior view showed very little change as compared with previous films (fig. 10).

After a short period of observation a Smith-Petersen nail was introduced through the neck of the femur and into the capital epiphysis, causing fixation with practically no displacement of the epiphysis from its normal position

Fourteen months after the original examination the patient walked without any limp and had no discomfort in the hip. There was shortening of the leg of about half an inch. Roentgenograms showed the epiphysal line almost completely closed by bony union. The capital epiphysis was in good position (fig 11).

OSGOOD-SCHLATTER DISEASE

In Osgood-Schlatter disease the essential lesion is a necrosis of the epiphysis of the tibial tuberosity with a certain amount of disability. It is more common among boys than among girls. Most observers believe that trauma is the inciting if not the actual cause. Numerous instances of the disease have been reported in youths who have suffered multiple injuries—of more or less minor degree—while engaged in athletic contests and similar strenuous exercises. There are local pain, swelling, heat and definite tenderness to palpation. The findings, as a rule, are out of all proportion to the extent of the trauma. Indeed, there may be no history of injury. Motion of the knee is usually free, but there may be pain over the tibial tubercle when the knee is flexed.

Roentgenographically, thickening of the patellar ligament at its insertion is a valuable sign, and films should be made of such quality that soft tissue detail is well

Fig. 10 (case 2).—Anteroposterior and lateral views of hip, showing beginning displacement of the capital epiphysis—shown best in lateral projection

visualized. Comparison films of the opposite knee are valuable. Sutro and Pomeranz⁴ state that this swelling of the patellar ligament may occasionally be demonstrated before there is any clinical evidence of its presence. The tibial tuberosity appears to extend downward in a tongue-like process from the anterior surface of the proximal epiphysis, but usually there are separate centers of ossification for the tuberosity. In the presence of necrosis, fragmentation and irregularity in outline and density are observed, as a rule. There may be small calcified particles adjacent to the anterior surface of the tuberosity, extending into the patellar ligament. As the disease progresses, the fragmentation and displacement of the calcified particles may become more prominent and widespread. In some cases the calcifying tuberosity appears to be separated from the underlying metaphysis by a wider cartilage zone than is normally present.

Considerable caution is needed in evaluating the bone changes in these cases, as a study of the knees of children in this age group will show a surprising variation in the development and calcification of the tibial tuberosity. It is necessary to examine the clinical findings and in many cases to demonstrate the confirmatory thickening of the patellar ligament.

⁴ Sutro, C. J., and Pomeranz, M. M.: Osgood Schlatter's Disease, Arch. Surg. 51:807-812 (Nov.) 1935

Treatment usually consists in conservative immobilization of the knee joint with relaxation of the patellar ligament. There may be a residual thickening and prominence of the tibial tuberosity.

CASE 3—T. G., a boy aged 13 years, had experienced pain in both legs just below the knees during the past month. This was accentuated by exercise, such as playing football, and definitely relieved by rest. Examination showed swelling and tenderness on palpation over both tibial tubercles but of slightly greater degree on the left. There was no redness or other sign of an inflammatory process.

Roentgenographic studies revealed thickening of the soft tissues over the epiphyses of both tibial tubercles with irregularly outlined epiphyses, and loose calcified bodies in the soft tissues over the tuberosity on the left side (fig 12 A).

Under a protective regimen the symptoms and signs regressed (fig. 12 B) and the patient had no further trouble until he began playing football seven months later, when symptoms recurred over the right knee. After two months' rest the symptoms again disappeared.

KÖHLER'S DISEASE OF THE TARSAL SCAPHOID

In Kohler's disease there is a necrosis or change in the ossification of the tarsal scaphoid. The condition occurs between the ages of 3 and 10 years, with a peak incidence at 5 and 6 years, and is more common in boys.

Fig 11 (case 2).—Anteroposterior and lateral views of hip ten months after nailing. Epiphysis shows very little displacement, and epiphysis is closing.

It was first described by Kohler in 1908. Symptoms may be slight or even nonexistent. In some cases attention is drawn to the condition by a swelling over the dorsum of the foot associated with local pain or tenderness. Occasionally it may be discovered incidentally during routine examination of the foot.

In these cases the ossification nucleus of the scaphoid is usually smaller than normal and much more dense than the other tarsal bones. It may retain its usual shape or be only slightly irregular in contour. The cartilage around it may be of normal thickness, so that there is no approximation of the cuneiform bones and the astragalus. The other tarsal bones usually present a normal appearance. Cases which have been followed show evidence of restoration to normal size and shape or only slight irregularity in outline and density after several years. A number of instances of bilateral involvement have been reported.

CASE 4.—T. G., a white boy aged 3 years, complained of pain in the foot. This had begun five months previous to admission and was attributed at that time to the wearing of tight shoes. Pain and associated swelling had persisted to such a degree that the child was unable to bear his weight on the foot. The swelling, however, had subsided gradually. The general health was good.

Examination disclosed slight increase in local heat together with moderate redness over the scaphoid area. There was some

swelling in this region but very little tenderness on palpation. Active motion of the foot was free and relatively painless.

Roentgenograms revealed arrest in development of the tarsal scaphoid with a considerable increase in density of the bone and swelling of the soft tissues over this area (fig. 13).

Whitman foot plates were applied, and within a short time the swelling regressed and the pain and tenderness disappeared.

Fig. 12 (case 3)—A, Osgood Schlatter disease of the tibial tubercle. It shows thickening of the patellar ligament and calcified areas in the soft tissues. B, in three months the swelling of the soft tissues showed regression and the calcification increased.

FREIBERG'S INFRACTION OF THE SECOND METATARSAL

The condition originally reported by Freiberg in 1913 as infraction of the second metatarsal was later described independently by Kohler and is sometimes known by his

Fig 13 (case 4).—Köhler's tarsal scaphoiditis. Arrested development of tarsal scaphoid with increased density. Soft tissue swelling around this area.

name. It is a disease occurring most frequently in girls between 10 and 15 years of age but may be seen in slightly older persons. The chief clinical symptom is pain over the head of the second metatarsal, especially

on pressure. In some cases there is a definite history of injury. There may be soft tissue swelling over the area. The heads of other metatarsals may be involved, but this occurs only rarely. The disease may be due to the increased length of the second toe, which renders it more liable to injury from ill fitting shoes.

Fig. 14 (case 5)—Freiberg's infraction of the head of the second metatarsal. It shows typical necrosis of the head of the metatarsal, together with a similar involvement of the proximal phalanx of this toe.

The roentgenographic appearances are characteristic and similar to those of aseptic necrosis in other areas. There are flattening and widening of the head of the second metatarsal with shortening. The articular surface is irregular in contour and shows increased density. The distal half of the shaft is thickened, with loss of the metatarsal neck. The cortex may be thickened, as well as the circumference of the shaft. The proximal portion of the phalanx is flattened and usually shows broadening. The articulation is broader than usual and may be strikingly irregular. Calcified loose bodies are sometimes demonstrable in the joint capsule.

A number of cases have been surgically explored, with subsequent pathologic study. In some cases there was a generalized thickening of the synovial membrane with no other macroscopic changes. In more advanced cases there were areas of subchondral necrosis of bone with necrotic lamellar spongiosa and irregular condensation. The necrotic area was separated from healthy spongiosa by a dense zone of connective tissue containing scattered areas of new bone formation.

CASE 5—G. P., a white man aged 20, complained of pain and tenderness of the second toe. There was no history of trauma. The condition had its onset two years previously
